Science and Manufacturing in Germany.—In an article in *Nature* for May 11th Prof. Armstrong gives an interesting account of the chemical research laboratory attached to a dye works at Elberfeld, and is moved to speak of the absolute necessity for a proper recognition of science by our own manufacturers in the following terms:—"A true conception of what a chemist is, what he is called on to do and to know in this age of progress, must arise in high quarters and especially among our manufacturers. Our children must be properly taught at school and trained to work as well as to play, and we must cease to worry their lives at college by insisting on the study of a multiplicity of subjects, and no longer attempt to develop a Chinese system of examinations. Surely it is time that we realised that our examination system is a fraudulent failure. In Germany the victory has been gained wholly and solely through the agency of the universities; here we are still dominated by influences which had their origin in the monkish cell, and our ancient universities do nothing to help us. The intolerant individuality which has enabled us to conquer and to govern where other nations have failed is of little use in an industrial war against the most systematically instructed people in the world, whose weapons are scientific research and scientific method, and who have been careful to 'organise victory' to use Huxley's expression in his remarkable letter in *The Times*, at the time that a proposal to establish an Imperial Institute was under discusion. Huxley warned us six years ago of the fate that awaited our industries if we did not organise victory. I fear that so far as chemistry is concerned, our insular conservatism still leads us to turn a deaf ear to all such warnings, and that the only change is that we are six years nearer to our fate."

Earthing Device for Transformers.—Our readers will remember that under certain regulations made by the Board of Trade, it is necessary to provide some form of safety device which will prevent a dangerous voltage from arising on low-pressure circuits fed from high-pressure mains. The Sharp and Kent system of interposing a layer of wire between the windings of a transformer was the first to receive official sanction. The subjoined notification shows that for this purpose the well known earthing device invented by Major Cardew has also been approved:—

Whereas, in certain regulations made by the Board of Trade under the Electric Lighting Acts, 1882 to 1890, and certain Provisional Orders and Licenses granted under those Acts, it is provided that where the supply of energy is transformed at a converting station, some means or apparatus approved by the Board of Trade shall be provided which shall render it impossible that the low-pressure distributing mains shall be at any time charged to a dangerous difference of potential from the earth, owing to any accidental contact with, or leakage from, the high pressure system, either within or without the converting station.

And whereas in such regulations it is also provided that where any transforming apparatus is installed on a consumer's premises, some means or apparatus approved by the Board of Trade shall be provided, which shall render it impossible that the low-pressure service lines and consumer's wires shall be at any time charged to a dangerous difference of potential from the earth owing to any accidental contact with, or leakage from, the high-pressure system either within or without the transformer.

Now, therefore, the Board of Trade approve of the apparatus known as the Cardew earthing device of the pattern deposited at the Board of Trade Laboratory, sealed, and numbered 3, 3A, and 3B, for use under such regulations.

Provided that in all cases in which such devices are used suitable quick-action fuses or cut-outs are inserted in the high-pressure circuits, and that in any case where the high-pressure current to the transforming apparatus may exceed 30 amperes, two such devices at the least shall be used.

Signed, by order of the Board of Trade, this twentieth day of June, 1893.

(Signed) FRANCIS J. S. HOPWOOD,
Assistant Secretary Board of Trade.

Magnetic Qualities of Iron.—A Paper by Prof. J. A. Ewing, and Miss Helen G. Klaassen, Lecturer in Physics, Newnham College, has been communicated to the Royal Society. The Paper describes a series of observations of magnetic quality in various specimens of sheet iron and iron wire. A principal object was to determine the amount of energy lost in consequence of magnetic hysteresis when the iron under examination was carried through cyclic magnetising processes between assigned limits of the magnetic induction **B**. Many cycles were gone through in the case of each of the specimens, the limits between which **B** was reversed being varied step by step in successive cycles, to allow the relation of the energy expended or of $\int \mathbf{H}\, d\mathbf{I}$ to **B** to be determined. The iron examined was, for the most part, thin sheet metal or wire such as is used in the construction of transformer cores. The experiments show that there are marked differences in the values of $\int \mathbf{H}\, d\mathbf{I}$ in different specimens, some nominally soft iron requiring two and even three times as much work to be spent in reversing its magnetism as is required in the best iron. They show, further, that great permeability does not necessarily imply small hysteresis losses. It is shown that although the formula proposed by Mr. C. P. Steinmetz ($\int \mathbf{H}\, d\mathbf{I} = c\,\mathbf{B}^{1.6}$) may serve fairly well as an approximate statement of the relation within those limits of **B** which are important in practice, it fails when applied to the more extreme portions of the curve. The Authors go on to describe a second group of experiments, in which direct measurements were made of the heat developed in magnetic reversals. The method consisting in using two rings, alike in all respects, with divided magnetising coils, was described in *The Electrician*, Vol. XXVII., p. 631. The Authors could not detect any difference in the amount of energy consumed in the core when the "load" was taken off or put on the secondary. In a third group of experiments the magnetic curve tracer was used. The time-lag in magnetisation is well shown by the curve-tracer, and the effects are compared of the same cycle of magnetic force gone through at various speeds. It is shown that in solid bars 1·9 cm. in diameter, especially in soft iron, remarkable evidences of time-lag are seen, even when the period of magnetic reversal is as long as 3 seconds. The work spent per cycle is maximum at a particular frequency, which in such bars is very low.

Cheap Gas Engine Working in Belfast.—In connection with the meeting of the Gas Institute, says the *Journal of Gas Lighting*, it should be recorded that an interesting and important illustration of the efficiency of gas-engines to compete with steam-engines for ordinary mill work was afforded at the linen factory of Messrs. Thompson, Rogers, and Co., in Belfast. There is one Tangye gas-engine of 100 H.P. at work, supplied with gas from a Dowson producer; but it is stated that as the demands upon the establishment increase two more engines of the same size will be put down. Gas-engines of 100 H.P. and even more have frequently been heard of, but seldom seen. Here we have an example of a gas engine capable of indicating 100 H.P., that has been working every day for the past three or four months to the complete satisfaction of the owners, and supplied with Dowson gas from a generator consuming anthracite coal after the rate of 2½ tons per week, costing on the spot 20s. per ton. The necessary attendance is given by one handy man, whose wages are £1 per week; so that the special expenses of working under this system are £3. 10s. per week. This, of course, is exclusive of wear and tear and interest on the Dowson part of the apparatus. The question may be asked: How does this plant compare with a coal gas supply? In the circumstances, the millowners are doubtless pursuing the cheapest plan; for, taking the consumption of coal gas by a Tangye engine of large size at 25 cubic feet per indicated horse-power per hour, the consumption for 100 H.P. for a working week of 56 hours would amount to 130,000 cubic feet, which would cost £14. 12s. 6d. There is plenty of margin between this figure and that of £3. 10s. already given to pay for interest, wear and tear, depreciation, rent of space, and extra labour, and still leave a difference in favour of the Dowson gas. With regard to steam-power, at the rate of 3lb. of coal per indicated horse-power per hour, the consumption of a 100 H.P. boiler would be 7½ tons per week, costing between £6 and £7 on the spot. Upon the power actually used in the mill the fuel comsumption is about 1¼lb. per indicated horse-power per hour, a sufficiently low average on which to congratulate the designers. It is an additional recommendation for gas-engines in mills that the convenience of having the power in 100 H.P. units enables it to be put down wherever required. This is a great consideration, since it means a saving of the cost and friction of the countershafting that in a steam-driven mill runs away with a heavy proportion of the total power developed by the main engine.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 119.*)

§ 14. Series, Shunt, Compound, and Separate Excitation.

It is of the utmost importance to fully appreciate the differences between the various methods of exciting the field-magnets, as all are not equally well adapted for all kinds of work, some being specially suitable for one class, and worse than useless for others. It is probable that the connections of the several windings are well known to most readers; yet it will serve to fix ideas and to give a firm grip of the various purposes to which each type of machine may be most profitably applied if the following sets of diagrams are carefully examined.

In each set the first figure shows simply the diagram of connections, irrespective of the arrangement and number of the field coils and poles.

The second figure refers to a dynamo wound as indicated in the first figure, and shows the order of the curve connecting the terminal, or omnibus bar pressure with the main current.

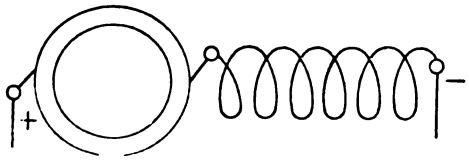

Fig. 15A.—Series Winding.

The third figure refers to a motor wound in the same style, and indicates roughly the shape of the curve connecting the number of revolutions per minute with the main or armature current.

The dynamo speed is in each case assumed to be constant, and so also is the pressure at which current is supplied to the

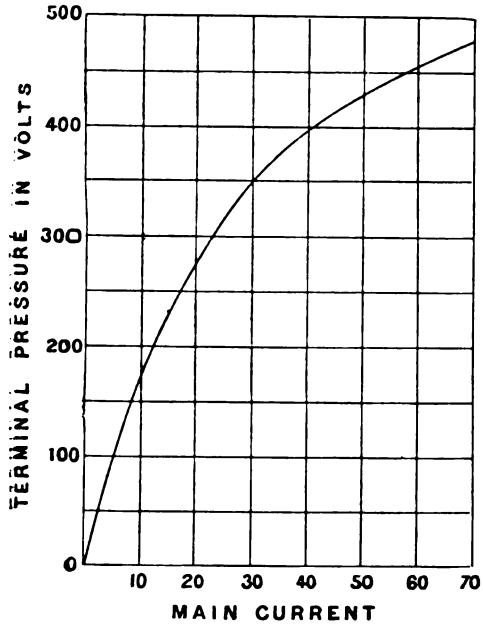

Fig. 15B.—External Characteristic Curve of Series Dynamo.

motor. These conditions are usually essential, and are conformed to, as nearly as possible, in all central stations.

The diagrams are so explicit as to need little comment, but a few suggestions may be useful.

The pressure in series-wound dynamos varies with the current, and hence these machines are only suitable for working on a constant resistance, such as a definite number of arc lamps or a fixed number of incandescent lamps; they are more especially adapted for the former work. They present one very apparent advantage in the fact that, since the main current passes through the field winding, the number of turns of wire on the magnets is comparatively few, and the wire is large, and therefore strong. High insulation resistance is thus easily obtained without mechanical difficulty or the use of costly material. For power purposes this winding possesses special value. Consider Fig. 15C, which refers to a series motor running at constant pressure. It will be seen that as the

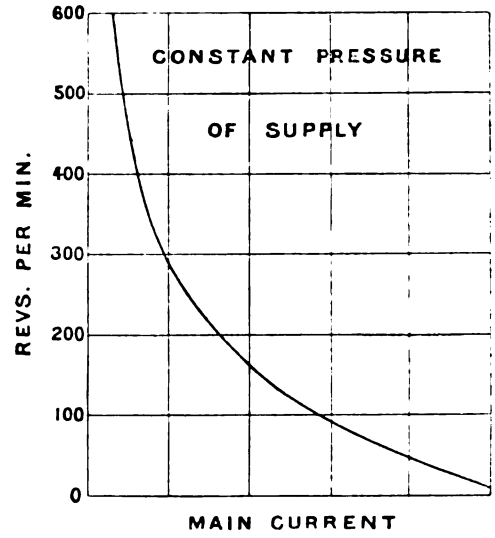

Fig. 15C.—Mechanical Characteristic Curve of Series Motor. Abscissæ Proportional to Torque.

current in the motor is increased the speed decreases, which is equivalent to saying that the torque varies inversely with the speed. Now, look at the series dynamo curve, Fig. 15B. As already pointed out, the pressure increases with the current, which is exactly the condition of supply to make the series motor run at a uniform rate of speed. Therefore, if a series-wound dynamo be coupled to a series-wound motor, and be driven at a constant speed, it will supply current at a pressure varying directly as the current and the motor will tend to run at a constant speed. This is such an important problem in the electric transmission of power that it will be referred to again, and the conditions for success examined more closely.

Series motors are suitable for a variety of purposes, and are generally used where a large torque is required at starting, and a fairly constant load obtains afterwards. When run off constant-pressure circuits, they are regulated by a variable resistance placed in series with them, and altered by hand as occasion requires.

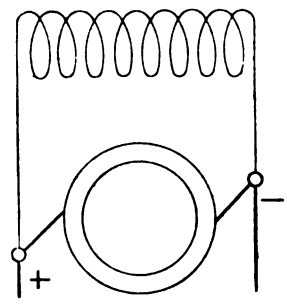

Fig. 16A.—Shunt Winding.

The *feature* of a series motor to be specially remembered is that the torque is greatest at starting, when the current is a maximum. This is so because the main current passes through both field and armature coils, and magnetises them to the greatest possible degree.

Shunt-wound dynamos give variable current at fairly constant pressure. They are therefore suitable for running loads, such as banks of lamps, which require varying power; and also *series-wound motors with constant loads*, or *shunt-wound motors with varying loads*. This is seen to be the case by comparing the shunt motor mechanical curve (Fig. 16C) with the shunt dynamo curve (Fig. 16B). The shunt motor when supplied at constant pressure maintains a fairly uniform rate

* All rights of reproduction reserved.

Digitized by Google

of rotation with varying load; the shunt dynamo *approximately* conforms to the supply conditions.

The shunt motor is not so well adapted for starting against a heavy torque as the series motor. For the shunt field excitation cannot exceed that determined by the supply pressure; and a sudden rush of current through the armature at starting tends to weaken the field magnetism unless the brushes have a forward lead, when there will be considerable sparking. When starting a shunt motor, the field circuit should be first closed, and time allowed for the magnets to become fully excited before the armature circuit is closed through the starting resistance, always used with these motors. After the armature has commenced to revolve, the resistance may be gradually cut out and the speed raised to its normal value.

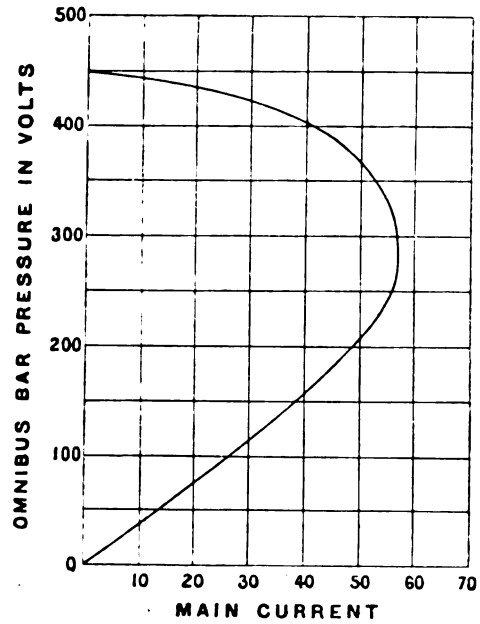

FIG. 16B.—External Characteristic Curve of Shunt Dynamo.

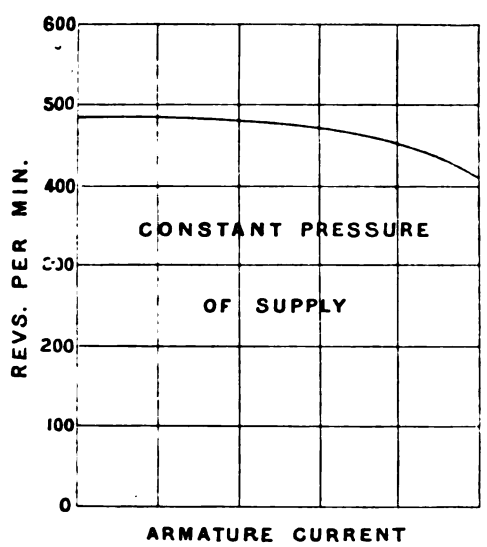

FIG. 16C.—Mechanical Characteristic Curve of Shunt Motor. Abscissæ proportional to Torque.

The *feature* of a shunt motor to be specially recollected is that it will run at nearly constant speed, with varying load, when supplied with current at constant pressure. This is the supply-condition of nearly all central-power stations, and hence shunt-motors have a special field in this connection.

As will be gathered from Fig. 17A, compound winding is a combination of the shunt and series methods of excitation. The shunt coils may be coupled across the brushes in "short shunt," or across the mains in "long shunt," as shown in Fig. 17A. The theory is as follows:—The shunt coils give an excitation proportional to the terminal pressure, and the series coils an excitation varying with the armature or the main current, according as the long or short shunt be adopted. It is evident that, by suitably proportioning the two windings, the external characteristic, Fig. 17B, can be made to slope at any angle to the current line; or, briefly, the pressure may be made to increase with the current, and, compensating for the fall in the feeders, maintain a constant pressure at the centre of distribution. The chief difficulty with high-tension compound dynamos is the shunt windings, which consist necessarily of many turns of fine wire, and give trouble from a variety of causes, besides being costly.

The mechanical characteristic of the compound-wound motor is shown in Fig. 17C. It will be seen that there are two methods of coupling up the coils, as suggested in curves 1 and 2. In the top curve the shunt and series excitations are differential, *i.e.*, the series coils demagnetise the field-magnets; in the lower curve they are cumulative, and both act in the same direction. The differential coupling is theoretically the better arrangement, and gives a more constant speed than even a shunt motor, as is apparent from equation (6) $E_m = C_a N_a n \frac{10^{-8}}{60}$, where E_m is the motor armature counter-electromotive force, C_a the number of armature conductors, N_a the lines of force, and n the revolutions per minute. Since C_a is constant, and N_a may also be regarded as such when a constant pressure acts on the shunt coils, it is clear that the speed, n, varies directly as the counter electromotive force, E_m. And the armature reactions do not affect the problem if we assume the current to have no effect on the value of N_a. Now,

$$E_m = e - i_a r_a,$$

where r_a is the armature resistance, and i_a the current in the armature, and e the pressure of supply. It is clear that E_m varies inversely with i_a, and, therefore, the shunt motor tends to slow as the current increases (for the speed is pro-

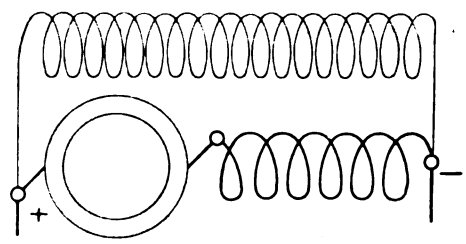

FIG. 17A.—Compound-Winding Long Shunt.

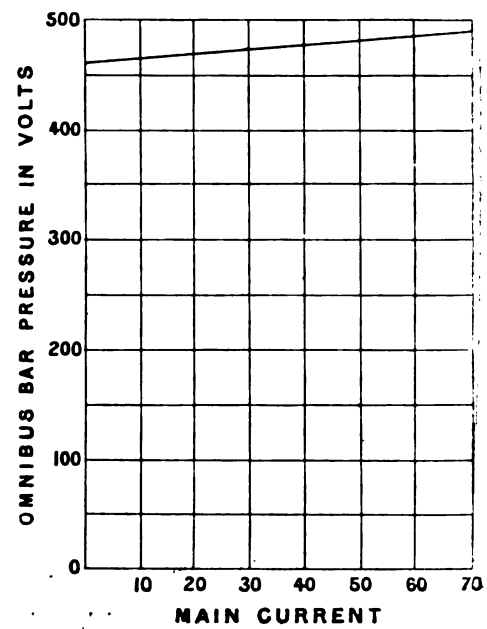

FIG. 17B.—External Characteristic Curve of Over-Compounded Dynamo.

Digitized by Google

portional to E_m). Referring again to equation (6) it is seen that to prevent this falling off in speed it is necessary to decrease the lines of force, N_a, in the same proportion as the fall of counter-electromotive force. This is most readily accomplished by decreasing the excitation, either by intercalating resistance in series with the shunt circuit, or by adding compound series coils wound in an inverse sense to the shunt turns. The armature reactions always weaken the main magnetic field, and therefore tend to make a shunt-motor run at a constant speed. It is thus possible to obtain nearly a

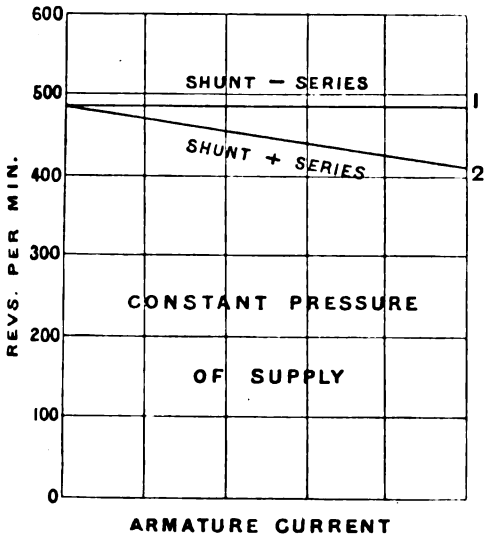

Fig. 17c.—Mechanical Characteristic Curve of Compound Motor. Abscissæ proportional to Torque.

straight line speed regulation with a well designed shunt-motor. A motor armature, then, should have a very low internal resistance, the smaller the better.

The cumulative method is more frequently used, for although it obviously does not regulate so well as a simple-shunt motor, yet it combines, to some extent, the starting power of the series winding with the speed regulation of the shunt. Sometimes a few series-turns are wound on large shunt motors, and are used only at starting, being short-circuited, as soon as the armature is fairly under weigh.

Broadly speaking, differentially-wound compound motors do not seem to be a success, and except for the few cases where absolute regularity of speed is required, they certainly have not found favour. Cumulative compound motors have also a

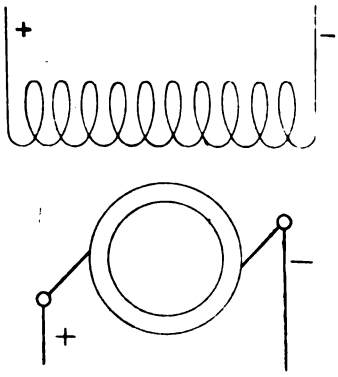

Fig. 18a.—Separate Excitation Winding.

very limited field of usefulness, well-designed shunt machines being more efficient, and giving better speed regulation. Yet there are some few applications where this winding will meet the conditions better than any other.

The *feature* of compound-winding to be specially noted is that, by applying it to the generator, the pressure at a distance point can be maintained automatically constant with varying current.

The idea of separate excitation is so easily grasped that there is no need to do more than refer to Fig. 18a, which is a diagram of the connections, the top scrolls representing the field-magnet coils. It is obvious that the number of turns on the field-magnets and the gauge of wire can be varied to suit the exciting current as long as the necessary excitation is provided. In Fig. 18b the external characteristic of a separately excited dynamo is shown at curve 3. It will be noticed that the

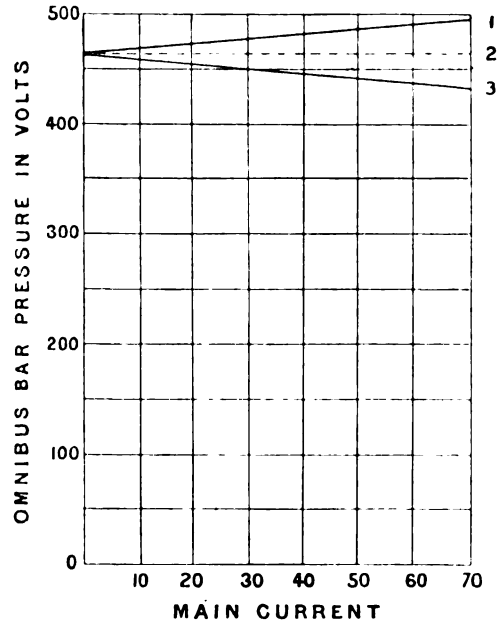

Fig. 18b.—External Characteristic Curve of Separately Excited Dynamo with Constant Excitation.

pressure falls as the output is increased, owing to the volts lost over the internal resistance of the armature. To obviate this the excitation must be proportionately augmented, so as to give curve 2. And if it be desired to compensate for the fall of pressure in feeders, then the exciting current must be still further increased until the slope of curve 1 suits the required conditions. The regulation can be accomplished automatically

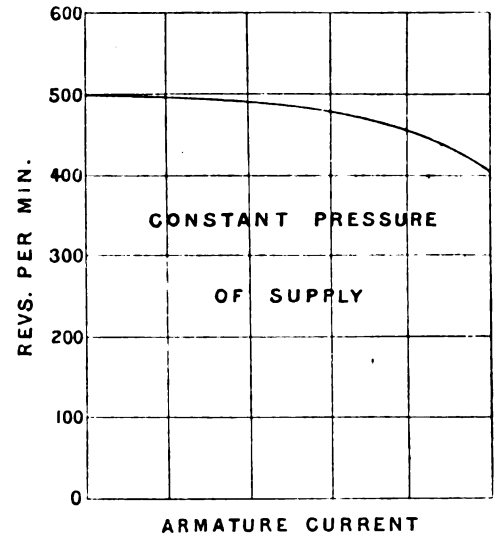

Fig. 18c.—Mechanical Characteristic Curve of Separately Excited Motor. Abscissæ proportional to Torque.

by some mechanical device controlled electrically; but it is usual in central stations, where this type of machine is most frequently used, to alter the excitation by hand.

The separately excited motor is not as yet much in use, but it will steadily grow in favour as transmission of power by electricity becomes more general. The mechanical characteristic of this type of motor, supplied at constant pressure, is shown in Fig. 18c. The fall of speed with increase of load can be compensated by *decreasing* the excitation either by hand regulation or reversed series coils.

Digitized by Google

These motors are specially adapted for large powers, because since the main current only passes through the armature, a high pressure can be safely used, and, moreover, the speed regulation is much superior to that obtainable with the series-winding. The objection is the independent source of power for the exciting current, which will probably have to be supplied in most cases from accumulators. Yet it must be recollected that a small shunt-dynamo, driven by the large motor will not only charge the cells, but also excite the motor field-magnets after the proper speed is once attained; and, further, this dynamo is available for lighting during the period the motor is at work.

The advantages of separate excitation are: firstly, the dynamo fields can be excited at a low-pressure, and hence are free from insulation troubles; secondly, lightning discharges are less likely to affect the magnet coils, since they are not connected to the line circuit (unless reversed series coils be used); and, thirdly, the pressure at any distant point can be easily varied at will. And with motors a high-pressure service is permissible, and the speed can be regulated either by the dynamo or motor exciting current.

(*To be continued.*)

ELECTRIC LIGHTING IN BARCELONA.

The electric light was introduced into this town by the Sociedad Española de Electricidad in the year 1882, the first operations consisting in running a few arc lamps from Gramme dynamos, which are still in use. At the present time, besides the glow lighting, there are 315 arc lamps at work, each taking 15 amperes at 50 volts. The earliest attempts at glow lighting were on the direct-current series system, but were not successful, but during April, 1891, the parallel-transformer, high-pressure system was adopted. There are now some 12,000 10 c.p. glow lamps connected to the transformers. The central station is situated close to the docks and town, the site being very convenient for coaling. There are in all nine steam engines, by various makers, viz., two 100 H.P. Corliss condensing engines, driving a line of counter-shafting for arc-light machines; two 150 H.P. condensing engines, driving Ferranti alternators by means of ropes; two 60 H.P. vertical engines, direct-coupled to dynamos for emergencies; one 60 H.P. Corliss condensing engine, which is used for driving a Mordey alternator by day and arc lighters by night; one 40 H.P. engine for a private arc circuit; besides one 300 H.P. compound condensing engine, which has just been added for driving a large Ferranti alternator. There are seven boilers, two of 200 H.P. and two of 100 H.P., of the water-tube type, and one 60 H.P. Lancashire boiler. These all supply steam at 85lb. pressure, but in future extensions it is intended to work up to 110lb. It will be seen that the plant is of a very mixed type, and much of it, being of old patterns, has a low efficiency. The arc lighting, for instance, is carried out on a system designed by M. Gramme, the arcs being maintained in series of 10 to 20 lamps, and regulated by means of iron-wire resistances, which are thrown into or out of the circuit by hand. As most of the arc light machines are small, they have to be worked in series in order to get the required voltage. The efficiency of the countershaft and arc light system is only 50 per cent. Moreover, the tendency of the dynamos on this system to reverse polarity makes it necessary to provide every arc lamp with a reversing commutator, in order that the current shall be conveyed through the carbons in the right direction. This system, as can be seen at a glance, is not a satisfactory one, and a motor-commutator and transformer are being supplied by Messrs. Ferranti and Co., for the purpose of running the arc lamps with a rectified current from the alternators. This would raise the efficiency from 50 to 80 per cent., and would halve the cost of maintenance.

The 300 H.P. Ferranti alternator is mounted on a cast-iron sole plate, and, for convenience in cleaning or repairs, is made in two halves, which can be moved apart by means of a screw arrangement. The field-magnets consist of 28 pairs of bobbins, 14 pairs on either side, and are built up of sheet-iron stampings pressed into the form of a horse-shoe magnet. The stampings are held together by iron rivets, and the magnets thus formed are bolted to the cast-iron frame. The armature is built up of 28 bobbins, which are coupled up into two series arranged in parallel. Attached to the bobbin-holders are a number of metal rings, which act as a fan, and cause a ventilating draught through the armature. This alternator is excited by means of a direct-current Statter dynamo, the armature of which is mounted on the alternator shaft. The exciter supplies a magnetising current of 50 amperes at 110 volts. The bearings of the alternator are of the swivel-ball pattern, and are provided with water glands. The linings, which are of white metal, are lubricated with oil supplied from force pumps. These pumps are worked by eccentrics on the alternator shaft, and supply the oil at a great pressure to the bearings, whence it drains into a cistern at the side of the machine, and is pumped back again to the bearings. In the event of either of these pumps failing, oil is supplied from a cistern about 15ft. above the dynamo, the height giving a head sufficient to force the oil between the bearing surfaces.

This machine is run at a speed of 295 revolutions per minute, and gives 90 amperes at 2,600 volts. Its height over all is 9ft. 6in., and the floor space covered by the bed is 10ft. 8in. by 8ft. 10in. The diameter of the armature is 8ft. 4in., and of the armature boss 5ft. 3in., and the clearance between the armature and the field-magnets is 1¼in. The shaft, which is 12ft. in length, is set in bearings of 2ft. length.

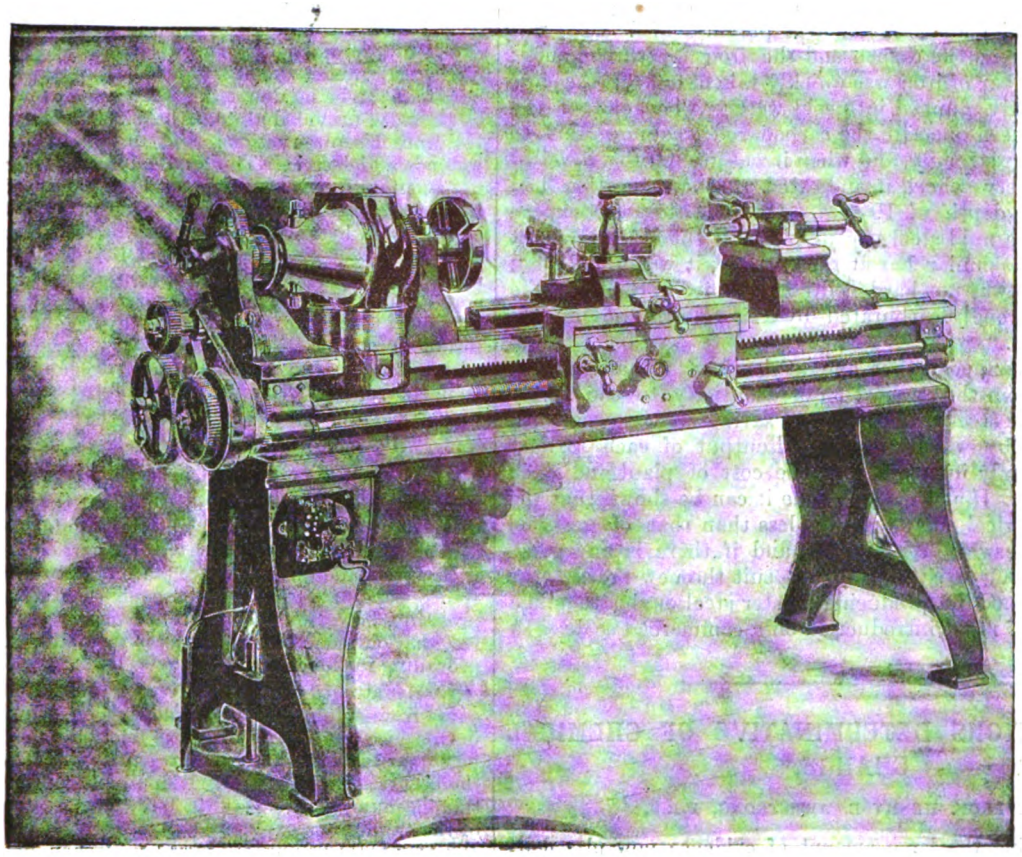
The main distributing switchboard for the glow lighting is made up of four feeder circuits and four distributors for the dynamos, each circuit having two sets of fuses and a double-pole switch, so that any circuit may be changed over instantly from one dynamo to the other. The sub-central point, or feeding point, is situated about a mile from the central station, in the midst of the densest part of the wiring. It consists of a small underground room, divided into three parts. The first part contains a board for the four feeders, and six pairs of fuses; the second part, another board, with ten pairs of fuses; and the third part, a telephone exchange for communicating with various points in the network of mains. Any of the four feeders from the central station can be plugged on to either of the ten distributing cables, and the voltage at the coupling boards is maintained at 2,550 volts, there being a 2½ per cent drop per mile in the cables. There is also, at this point, a large transformer which supplies a local low-pressure network at 105 volts. The various distributing circuits which leave the sub-central point are carried to various parts of the town, and are again sub-divided at numerous junction boxes. These boxes are placed in excavations under the footpath, and are lined with brick and cemented over. Air transformers are placed in these boxes, each transformer supplying the lamps within 100 yards radius of the box. The whole of the main cables are tested daily just before starting, and are tested by means of a vacuum tube several times during the day's run.

ELECTRIC MACHINE TOOLS.

Rather more than a year ago we commented on the numerous types of steam engines which have been designed for special purposes. The factory engine, the marine engine, and the locomotive differ so widely, both in general arrangement and in detail, that the casual observer might be excused if he asked whether so dissimilar machines had anything in common. We called attention to the apparent want of adaptability of the electric motor as generally made, not, indeed, that it cannot be applied to all sorts of duties, but that it is generally merely taken from stock and geared to the work by gear-wheels or belts. A recent article by Mr. Wheeler, one of the joint inventors of the well-known Crocker-Wheeler motor, shows that this apparently un-engineer-like principle of tacking a motor on to a machine is not so bad as it at first sight seems. In this article in the *Electrical Engineer* of New York a number of machine tools were illustrated, and in the majority

Digitized by Google

of cases the motor seemed to allow itself to be grafted into the machine and to form a part of it, in an unexpected manner. We applied to the General Electric Company, the agents in this country for the Crocker-Wheeler motor, for further particulars of these adaptations, and are enabled to illustrate a power lathe driven in this fashion. The armature of the motor, well boxed in, takes the place of the ordinary speed cone; while a starting and control switch placed, in this case, perhaps rather low, enables the turner to start and stop and to change his speed within limits, in a very simple manner. For continuous work of one kind, a change of speed is seldom required, and still less is a change of power or for large tools on which a variety of work is done, the direct application of a motor is more difficult, unless some sacrifice is made. Small as is the power, something better than toy motors, such as are used for driving fans and dentists' drills, is required. We were amused to learn from a correspondent that in his opinion one reason for the comparatively small demand for motors in this country is that "electricians in charge of central stations rather block the introduction of motors because they are trying to invent one themselves, or have a friend round the corner at the same work." The best arrangement of a motor will only be found by experience. In some cases it will no doubt be found possible to dispense altogether



demanded. For such work a motor thus fitted seems to be very useful, especially in driving milling machines, which are now gradually replacing other machine tools for many classes of work; and for polishing wheels the electromotor, applied in this way, seems to possess advantages over geared motors. For tools of this class, freedom from vibration is essential to good working, and high speeds are often requisite in dealing with certain materials; both of which *desiderata* can, in all probability, be supplied by a direct-coupled electromotor more perfectly than in any other manner. By means of a switch and resistance coils, the speed can be more or less economically reduced, but there is no possibility of altering the power as is done by the ordinary speed pulleys, unless these are retained and driven by the motor. It will be noticed that the traversing shaft in this lathe is driven by a belt and speed pulleys. If pulleys and belts are to be used for driving the main shaft of a machine, the building of the motor into the frame work is not so important, and we come back to the method adopted at Wolverhampton, Liège, Charlton, and other well-known examples of electrically-driven factories.

The small amount of power taken by machine tools must be measured to be believed, and no better way of measuring it is possible than with a motor, an ammeter, and a voltmeter. For American work especially, where one tool is kept to one kind of work, and where large quantities of work are turned out with little or no variation, it ought not to be difficult to select the right size of motor to give the best result. For jobbing, with overhead gear and belts, and to drive direct, as has been done in ship-building tools, drills, and the lathe fitted by Mr. Wheeler.

THE ACTION OF ELECTRICITY ON THE CARBURATION OF IRON BY CEMENTATION.

An interesting process has been devised by M. Jules Garnier for accelerating the carburation of iron. In the ordinary cementation process, the bars of wrought iron which require to be carburised are packed in layers in a mass of powdered carbon, and are sustained at a bright red heat for a time which depends on the size of the bars, and on the extent to which they have to be impregnated with carbon. Slight case-hardening will usually occupy only a few hours, while the complete production of blister-steel bars from merchant or puddled bar will take from ten to fifteen days. During the whole time, the stack must be kept at a high temperature, at, of course, a considerable expense in fuel. Blister steel is used to some extent in the arts, while case-hardening is largely resorted to in mechanical and electrical engineering; so that any modification of the process which will reduce the consumption of fuel, or accelerate the process, will be of no small importance.

It occurred to M. Garnier, whose experiments have been communicated to the *Académie des Sciences* by M. Moisson,

Digitized by Google

that it might be possible to increase the activity of the process of cementation by means of the electrolytic action of a current, using an anode of carbon and a cathode of the iron to be carburated, the electric current being passed while both cathode and anode were maintained at furnace temperature. To test this, a rod of carbon and a bar of extremely mild steel (0·1 per cent. of carbon) were placed end to end, and well insulated from one another, in a tube or barrel of some refractory material. This was then placed horizontally in a reverberatory furnace, heated by a blast of air supplied from underneath. While thus kept hot the carbon rod was connected to the positive, and the iron bar to the negative, pole of a Gramme machine capable of supplying a large current at low pressure.

A current of 55 amperes under a pressure of 7 volts was maintained between the carbon and the iron for three hours; after which the bar of iron was quickly taken out of the furnace and instantly plunged into cold water. The end of the bar which had been opposite the carbon rod was now able to scratch glass very strongly, and when it was ground to a bevelled edge at an emery wheel, it indicated that cementation had taken place to a depth of 10 mm. On repeating the experiment, but with a mild steel bar in place of the carbon rod at the anode, and a similar bar at the cathode, it was found that, while the anode was not hardened nor modified in the least, the cathode was strongly carburated by the electrolytic impregnation of carbon.

It would thus appear that one at least of the advantages to be derived from the application of electricity to the manufacture of blister steel is the immense saving in time occupied by the process, by which the annual output of each furnace can be very largely increased and the cost of plant and stock can be reduced. If at the same time it can be shown that the cost of the electrical energy used is less than that of the fuel which must otherwise be consumed, and if there is any possibility of modifying existing stacks to suit the new process, the electrolytic method of producing blister steel ought to stand a good chance of rapid introduction on a commercial scale.

THE CONDITIONS DETERMINATIVE OF CHEMICAL CHANGE.*

BY PROF. HENRY E. ARMSTRONG, F.R.S.

Notwithstanding the large amount of evidence now placed on record that substances commonly supposed to be capable of directly interacting do so only in the presence of at least one other substance, chemists do not appear to have arrived at any clear and consistent understanding of the conditions determinative of chemical change: as each fresh case is recorded we continue to express surprise, overlooking the fact that Faraday, in his early "Experimental Researches in Electricity," clearly foresaw what the conditions were, and that but a slight extension of his generalisations is needed to frame a comprehensive theory. The subject is of such importance that it appears to me desirable to discuss the bearing of recent observations, especially as they to some extent necessitate the modification of views that I have expressed elsewhere, and in order to attract the attention of physicists, to whom we must now look for guidance in these matters.

Eight years ago, in the course of the discussion on Mr. H. B. Baker's communication on "Combustion in Dried Gases" (*Chem. Soc. Proc.*, 1885, p. 40), I defined chemical action as *reversed electrolysis*; in other words, in order that chemical action may take place, it is essential that the system operated on comprise an electrolyte. I then pointed out that as neither hydrogen nor oxygen was an electrolyte, a mixture of only these two gases should not be explosive; and, moreover, that as water was not an electrolyte, and it was scarcely probable that water and oxygen or hydrogen would form an electrolyte, it was difficult to understand how the presence of water pure and simple should be of influence in the case of a mixture of hydrogen and oxygen. This forecast has since been verified, the remarkable series of experiments carried out by V. Meyer, in conjunction with Krause and Askenasy, having clearly demonstrated that the formation of water from hydrogen and oxygen takes place at an irregular rate, and is, therefore, dependent on the presence of a something other than water—I imagine an acid impurity. But this is a consideration which has not yet received the proper attention, and it is, therefore, desirable to emphasise its importance by reference to other cases. Mr. Baker's recent preliminary note on the influence of moisture in promoting chemical action (*Proceedings*, p. 229) affords several interesting examples. Thus, he states that neither does hydrogen chloride combine with ammonia, nor is nitric oxide oxidised by oxygen if moisture be excluded. In the former case, the addition of water should suffice to determine the combination, as water and hydrogen chloride together form a "composite electrolyte" (*cf.* Roy. Soc. *Proc.*, 1886, No. 243, p. 268). As neither nitric oxide nor oxygen, however, forms a composite electrolyte with water, in this case water alone should not determine the occurrence of change; but if by the introduction of a trace of "impurity" in addition to water the presence of a composite electrolyte were secured (however high its resistance, owing to the smallness of the amount of "impurity"), action would set in, and when once commenced would proceed at an increasing rate, as nitric acid would be formed and the resistance of the electrolyte would consequently diminish. On this account it will be a task of exceeding difficulty to experimentally demonstrate that nitric oxide and oxygen are inactive in presence of water alone; but there can be no doubt that such must eventually be admitted to be the case, provided always that it is permissible to extrapolate Kohlrausch's observations, and to conclude from them that *pure* water is a dielectric. The gradual increase in the rate of change here contemplated corresponds to the period of induction observed by Bunsen and Roscoe in their observations on the interaction of chlorine and hydrogen; the statement recently made by Bodenstein and V. Meyer (*Berichte*, 1893, 1,146) that a mixture of chlorine and hydrogen behaves irregularly on exposure to light is a valuable confirmation of Pringsheim's observations, and there is now no room for doubt that *pure* chlorine and hydrogen would be incapable of interacting. That no such irregularity is observed on heating iodine with hydrogen is not surprising, as hydrogen iodide would be formed from the very outset and the electrolyte present would exert a minimum resistance almost at once. There is, however, a significant difference in the behaviour of the two mixtures, as hydrogen chloride should behave as hydrogen iodide, so that the problem is but incompletely solved; it may be that the one mixture was more nearly pure than the other, or it may be that the formation of hydrogen chloride from hydrogen and chlorine, under the influence of light, is dependent on the presence of some particular substance, together with water, and does not take place under the influence of any substance capable of forming a composite electrolyte with water; probably, however, the difference observed is chiefly due to the fact that only one of the actions is reversible under the conditions prevailing in the experiments.

Lastly, attention may be directed to the formation of sulphuric oxide from sulphurous oxide and oxygen, which is readily effected in presence of a catalyst, such as finely divided platinum; it cannot be supposed that the mere presence of platinum would condition the occurrence of change, and doubtless moisture is also necessary, the platinum or other catalyst but serving to promote the oxidation of the sulphurous oxide at a temperature considerably below that at which sulphuric oxide decomposes when heated. The action of surfaces generally may well be of this character, and the converse influence they so frequently exercise is probably an effect of the same order.

I have elsewhere raised the question whether there may not be a difference between actions taking place under the influence of low and of high electromotive forces—whether water, *per se*, may not be an electrolyte towards high, although not towards low, forces in the case of high temperature changes, or those brought about under the influence of the electric spark, for example. More attentive consideration of the subject has led me to think that this is not the case, and that we must treat high temperature changes such as occur and are involved in gaseous explosions in the same way as those occurring under ordinary conditions and at low temperatures. From this point of view, Mr. Baker's statement that ammonia and hydrogen chloride do not combine is of extreme importance; the formation of ammonium chloride from these two compounds apparently involves no interchange, but a mere combination of two substances each endowed with considerable "residual affinity," and there is no reason why a distinction should be drawn between such a case and that afforded by, say, *atoms of hydrogen and oxygen*, the difference being, it would seem, one of degree only: in fact, I am no longer inclined to believe that atoms are capable of directly uniting. In all cases at least one function of the (composite) electrolyte would appear to be that of providing the necessary "mechanism" whereby the degradation or discharge of the energy is effected. If this argument be sound, its logical extension involves the conclusion that *pure* gases should be dielectrics, *i.e.*, that the passage of an electric discharge through a gas like that of an explosive wave through, say, a mixture of hydrogen and oxygen, can only take place if an electrolyte be present. Hitherto but little attention has been paid to the electric discharge in gases which have been highly purified. The peculiar behaviour of Tesla tubes, referred to by Mr. Crookes in the discussion on Mr. Shenstone's Paper on the formation of ozone, is, perhaps, explicable from this point of view. It may be that the atmosphere within the

* Reprinted from the *Proceedings* of the Chemical Society.

Digitized by Google

tube does not become conducting until sufficient moisture and "impurity" have been projected from its sides. It is conceivable that a similar explanation may hold good in the case of Prof. Schuster's observation, that it is possible to urge a current of low electromotive force across a gas subjected to a high electromotive force in itself insufficient to cause a discharge in the gas; the atomic dissociation hypothesis put forward in explanation of the phenomenon does not appear to me to be sufficient.

Finally, the question arises, Can no line be drawn; are no two pure substances capable of combining or interlacing, for example, water and sulphuric anhydride? There is little to guide us here, but it seems not unlikely that water has special properties which enable it to act directly; moreover—perhaps because—in such cases composite electrolytes would result. Ammonium chloride, so long as it remains solid, is clearly a compound of a different order, and it may well be that compounds of this type are in no case directly obtainable from their constituents, because, under the conditions under which they are formed, they cannot behave as electrolytes.

Apparently, in all cases in which molecular aggregates are formed—as in the case of solutions—we are dealing with dissociable and dissociating systems, and it is not improbable that we may ultimately find an explanation of the mechanism of such changes in this fact.

At present there is no information forthcoming whether simple electrolytes, such as fused silver chloride, for example, will condition chemical change in the way that water does; whether, for instance, silver chloride will condition the formation of hydrogen chloride from chlorine and hydrogen, so that a gas battery might be constructed of these three substances.

THE NATURE OF DEPOLARISERS.*

BY PROF. HENRY E. ARMSTRONG, F.R.S.

When an electric current is passed between plates of platinum through a solution of sulphuric acid, the hydrogen and oxygen are partly retained at the surfaces—and apparently also within the plates—and under these conditions are capable of interacting, as in the well-known Grove gas battery; so that in so far as the "gases" thus circumstanced are concerned the change may be expressed by a reversible equation. This reversal constitutes the well-known phenomenon termed polarisation by physicists.

Reversal owing to the retention of hydrogen in circuit is promoted to different extents by different metals—hence apparently the varying electromotive forces of single fluid cells containing different negative plates; and when the pressure is sufficient to retain the whole of the hydrogen at the plate, it becomes total—hence it is, for example, that zinc does not dissolve in sulphuric acid under great pressure.

Various substances known generally as depolarisers are used to prevent the accumulation of products of electrolysis and the consequent reversal of the action—such as copper sulphate in the case of the Daniell cell, and "nitric acid" in the case of the Grove and Bunsen cells; but whereas the action of copper sulphate is easy to understand, that of "nitric acid" offers many difficulties. As the heat of dissolution of copper in dilute sulphuric acid is a negative value (about 12,000 units), the displacement of copper by hydrogen—*i.e.*, the heat of dissolution of hydrogen in copper sulphate—is a positive value, so that not only does the presence of the copper sulphate prevent the accumulation of hydrogen, but in removing hydrogen it also serves to increase the electromotive force of the cell from about $\frac{7}{8}$ths to about $\frac{7}{8}\frac{9}{0}$ths of a volt. The principle underlying this is extensible even to cases in which one part of the cumulative effect of the cycle of change is a negative value. Thus, although copper has a negative heat of dissolution, it will readily dissolve in dilute sulphuric acid if it be used in place of zinc in a Grove cell, the negative heat of dissolution of copper being more than compensated for by the positive heat of dissolution of hydrogen in "nitric acid"; and it is well known that copper dissolves in many weak acids in presence of oxygen. It is easy to understand how oxygen acts in such cases, but the facts show that the effect produced by "nitric acid" is not so readily interpreted, and their consideration raises important questions of general application.

Russell has shown that when "nitric acid" is freed from nitrous compounds it does not dissolve silver, but that action sets in when a trace of nitric oxide is introduced, and continues with increasing rapidity as the quantity of the nitrous compound—a necessary product of the action—increases; Veley's later experiments have shown that the same is true of copper, without, however, affording any further explanation of the phenomena. Although it is not to be expected that such metals would dissolve in nitric acid even when coupled with a relatively electro-negative conductor, as they have negative heats of dissolution; yet, if the acid also acted as depolariser, a cycle might be formed in which sufficient energy would be developed to condition change. It therefore follows that in such cases *nitric acid* does not act as the depolariser in accordance with the equation: $2Ag + 2NO_3H + ONO_2H = 2AgNO_3 + H_2O + NO_2H$, and that, in point of fact, the nitrous compound is the depolariser, although the nitric acid is the actual solvent of the metal, the hydrogen of the acid being virtually directly displaced by the metal with the assistance, however, of the current energy derived from its own oxidation by the nitrous compound.

But what interpretation is to be given of the behaviour of more active metals, such as zinc, magnesium, &c., which have positive heats of dissolution, and, therefore, are capable of dissolving in the pure dilute acid if coupled with a relatively negative conductor. Does nitric acid in their case directly act as depolariser? If it be capable of thus acting, such metals, even when uncoupled, should dissolve in the pure diluted acid. It is noteworthy that when such metals are dissolved in nitric acid hydrogen is sometimes evolved. It has been suggested that this hydrogen is derived from the interaction of the metal and water, but I cannot now regard this as a probable explanation; its production serves rather to suggest a deficiency of the depolarising agent, which cannot well occur if nitric acid be the depolariser. Indeed, if nitric acid be regarded as directly active, it is remarkable that in presence of the large excess of the acid which is always present any hydrogen should escape; and also that the reduction should extend so far as it often does, and not extend merely to the formation of nitrous acid. If, however, the acid be incapable of directly acting as depolariser, and a nitrous compound be the initially active depolarising agent, it is no longer surprising that, owing to the nitrous compound suffering further reduction, it should be deficient in parts of the circuit, and that, consequently, hydrogen should escape. Why the reduction should extend so much further when metals having positive heats of dissolution are used, however, still requires elucidation.

In the case of sulphuric acid, whatever metals be dissolved in the *diluted* acid, no reduction takes place; and it is only when the concentrated, and more or less heated, acid is used, that sulphurous oxide and other reduction products are obtained. It appears not improbable that reduction only takes place under conditions under which the presence of sulphuric *oxide* is possible, *i.e.*, that depolarisation is effected by sulphuric *oxide*, and never by sulphuric *acid*, although this latter may be regarded as the actual solvent of the metal. There is at present no evidence forthcoming to show that nitric acid can dissociate into the anhydride and water, and even if such a change took place in concentrated solutions, there is no reason to assume that it can also take place in dilute solutions, and that this is the explanation of the difference between nitric and sulphuric acids. It is well known, however, that nitric acid is resolved with extreme facility into nitrogen dioxide, water and oxygen, and that it is excessively sensitive to the action of nitric oxide—a trace of nitric oxide would therefore exercise a fermentative action and condition, the formation, it may be, of nitrous acid, or—as there is no evidence compelling us to suppose that the compound represented by the formula HNO_2 exists—it may be of nitrogen dioxide.* In this latter case, solutions of nitric acid would resemble concentrated sulphuric acid in containg a reducible oxide, and it may be that their depolarising action is initially exerted through such an oxide alone.

To arrive at a clear conception of the function of acids in dissolving metals, and of the nature of depolarising agents, it would, therefore, appear to be necessary to take into account many circumstances to which hitherto but little attention has been paid.

The Claude Phasemeter.—At the recent exhibition of the Société de Physique M. Claude showed an instrument for measuring the difference in phase between the current in a circuit and the impressed electromotive force. The principle of the instrument is as follows:—When a piece of soft iron, fixed to the end of a spring, is placed before the pole of an electromagnet having a permanently magnetised core and traversed by an alternating current, it is attracted and vibrates with the same period as the current. If the spring also carries a mirror from which a ray of light is reflected on to a scale, the length of the band of light produced will be proportional to the maximum displacement of the mirror. Two such electromagnets are used, acting on the piece of soft iron in opposite directions, and at such distances that they produce the same maximum deflection, one magnet being placed in series with the circuit, and the other joined to the ends of a non-inductive resistance. Under these conditions, the length of the band of light is proportional to the cosine of half the angle of lag.

THE NATIONAL TELEPHONE COMPANY v. THE ELECTRICAL INDUSTRY.

The Joint Committee of the Houses of Parliament which has been giving close attention to a large body of evidence for seven days, has had to consider much wider subjects than that for which it was summoned. The Committee was appointed at the instance of an application of the National Telephone Company, who felt that the time had come when they might make a powerful attack on all those who obtain statutory powers for using electrical energy. They sought to impose, by the assistance of Parliament, most onerous prohibitions and restrictions on any body who might accidentally inconvenience them. Practically the whole electrical engineering industry of the country was mercilessly attacked for the ends of one monopolist, and this not because its telephonic monopoly was in any way threatened, but because the imperfections of its single-wire system were likely to be brought to light.

The Telephone Company, employing as they do the most delicate instrument known to science, as far as varying or alternating currents are concerned, spread over the land a web of wires which are poorly adapted to their ostensible purpose of enabling conversation to be carried on, but which could hardly be better adapted to pick up every stray current or any inductive effects that might be present. If the Company, instead of attempting to crush all who annoyed or might annoy them, had agreed to compromise in a friendly way, on any of the many occasions when compromise has been suggested (as for example at the London Chamber of Commerce), some arrangement might have been suggested whereby a traction company might have increased the size of its return conductor, or have rearranged its feeders, or have

Digitized by Google

contributed towards the expense of altering any telephone wires which were actually disturbed. But such compromises are never attractive to monopolists. We do not complain of monopolies; they do excellent service, and service that could not otherwise be rendered so efficiently; but scratch a monopolist and you will find a tyrant.

The evidence placed before the Committee, as far as the telephone interests were concerned, dealt chiefly with leakage, insulation, and earth currents. One or two witnesses for the traction companies vainly tried to call attention to the effect of induction, but here the deficiency of the single-wire telephone circuit is so palpable, and the remedy so obvious, that the Telephone Company said but little about it. Curiously enough, the Plymouth Clause, the essential portion of which was printed on page 68 of our present volume, alluded to "injurious interference by induction or otherwise." The question of induction remains practically where it did before the Joint Committee sat. Not one of the high scientific authorities who were retained by the Telephone Company ventured to suggest any way in which an electric tramway could be erected so that a neighbouring single-wire telephone line should be undisturbed by induction. The National Telephone Company does not appear to care a rap whether this is scientifically possible or not, as their procedure at Salford and elsewhere plainly shows.

The question of leakage gave rise to two other inquiries: one, as to the electrolysis of buried pipes and conductors, which in no way affected the telephone interests, unless by adding to the difficulties which their opponents had to face; and the other, concerning railway telegraph signals. The provision of a metallic return for railway signals is, of course, a proper precaution. Mr. ASPINALL'S estimate of £48,000 outlay, and £7,700 a year maintenance is quite inexplicable; for a single return wire within a mile or so of the disturbance is all that is needed. Duplication of each wire seems to be, in many cases, not only unnecessary, but likely to lead to great complication. To the cost of such a return wire, a traction company might fairly be asked to contribute. Experiment would easily show how far disturbances are likely to extend; Mr. PREECE puts it at from half a mile to a mile. The sudden impulse due to a short circuit is to be feared rather than the working current. The electrolysis question appears to be the real matter of importance, although Mr. CROMPTON, speaking probably from an electric lighting point of view, says that it has been greatly exaggerated. In our leading article of March 24th last we alluded to the serious consequences which might result from a continuous passage of currents through the earth, and we have not hesitated to give the fullest publicity to various instances of electrolytic corrosion that have occurred. The earthing of the negative pole and proper regulation of the fall of volts on the return conductor ought to be a sufficient cure for traction work as it has been for electric lighting. Just at the time when the discussion on "earthing the middle wire" was being carried on in our columns, several engineers were becoming assured that the precaution which they had for some time adopted, of earthing their negative, was giving such good results that they could not contemplate the earthing of the middle wire. We could not get any of them at that time to definitely express their views in our columns, but this opinion may well be recorded on the present occasion. The evidence of Major CARDEW was of great interest and importance. He described the result of several accidents, but all of these, together with one mentioned by Dr. J. HOPKINSON, were due to actual contact. Even the ringing of the electric bell at Clapham-road was shown to be, in all probability, due to actual contact and not to stray earth currents. It still remains to be proved that any appreciable electrolytic corrosion is due to pure conduction through the soil; scientifically it is possible, but it is not yet within our experience. If a difference of six or eight volts is maintained at the ends of an earthed conductor, it is clear that, theoretically, corrosion should take place at the anode end. Major CARDEW makes the very reasonable suggestion that as the Board of Trade restricts the fluctuation of pressure on electric supply mains to three per cent. from the standard, they might, in an analogous way, restrict the drop in volts on an earthed conductor. This restriction would probably have been made sooner or later, and we have to thank the National Telephone Company for having given an opportunity for its discussion before any accident has made it a necessity. Major CARDEW said that he had made an examination of the condition of the line at Leeds, and intended to go there again, to see how the arrangement had worked after a year's interval. We understand that he has had the ground opened at several places, and has found no sign whatever of corrosion. Prof. DEWAR'S evidence was of a more theoretical nature. He fears that the polarising film of hydrogen which is supposed to protect buried pipes when connected to the negative pole, would combine with the nitrates in the soil, and that corrosion, presumably by the formation of nitric acid, would take place. How this could occur while the metal was still a cathode is not easy to see. It is perhaps a pity that Major CARDEW and the experts were necessarily unprepared for discussing this important question, but it is possible that had notice been given, the practical suggestions would have been swamped by a mass of theoretical considerations.

The report of the Committee will be awaited with interest. It is very unlikely that the cool demand of the National Telephone Company for the continued insertion in all Tramways Acts of the Plymouth clause will be granted unconditionally; if they wished to continue to get such clauses inserted as heretofore, it would have been better to have let the matter rest where it was. It is likely that a recommendation will be made to give them powers to go underground; but they will also be expected to take some steps to modify the crude and deficient system of lines which have led to the inquiry. The railway question should be easily settled, and details of railway construction being already under the immediate control of the Board of Trade, no difficulties need be apprehended. Some of the suggestions made by Mr. PEMBER in his speech, an abstract of which will be given in our next issue, were rather amusing. It might be enacted, "that in no case should a current be sent to earth (never mind who by) greater than some ascertained fraction of an ampere;" "it might be enacted that two wires should be laid so near as to prevent induction;" and "that it should be a sufficient compliance with the Act if the promoters, in constructing and maintaining their works . . . adopt the best-known means of insulating the conductor . . . ." We venture to suggest quartz pedestals and annular sulphuric acid cups as suitable for this purpose. We can sympathise with the National Telephone Company in the unfortunate quality of the work which they bought from the early companies, and the unproductive character of much of their capital; in the heavy royalty which they pay to the Government, which is certainly more in the nature of a fine; in their expensive way-leaves, and their uncertain tenure; in their inability to obtain statutory powers to go underground—overhead powers are another matter; but we cannot sympathise with their attempt to obtain protection for their imperfect system, which not only gives inefficient results, but has been used to retard the progress of other electrical industries.

ELECTRICITY AT FÜRSTENFELD-BRUCK.

The electrical utilisation of water-power is making far greater progress on the Continent than with us, owing, no doubt, largely to natural conditions. Whilst large transmissions have more interest for the engineer, it is the smaller applications of water-power to the generation of electricity that have the most social interest. Few localities have a Niagara at their disposal, but the towns and hamlets that could impress the services of a small amount of horse-power are numerous, even in the United Kingdom. It is from this point of view that it is well to occasionally take note of what small Local Authorities are

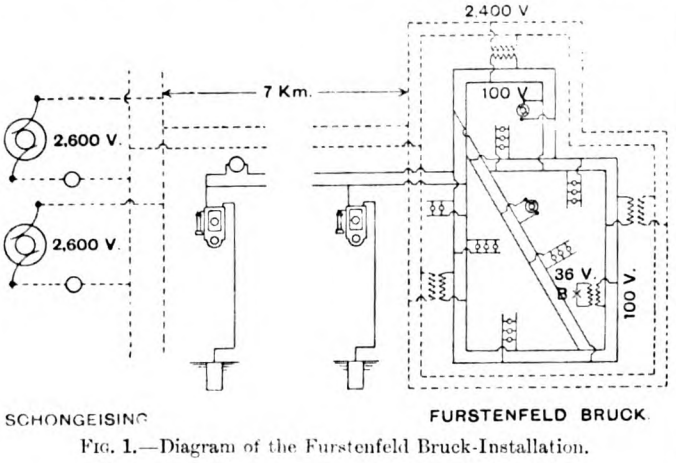

FIG. 1.—Diagram of the Furstenfeld Bruck-Installation.

doing on the Continent in the direction of utilising by means of electricity the hitherto wasted power of streams and rivers. We, therefore, take the following particulars with regard to a water-power installation from a well-illustrated little pamphlet sent us by Herr Oscar von Miller.

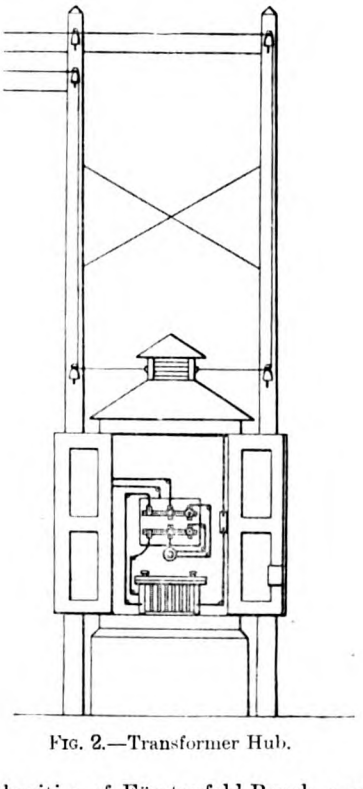

FIG. 2.—Transformer Hub.

The local authorities of Fürstenfeld-Bruck, a quiet Bavarian town of about 3,000 inhabitants, having purchased a mill site with a view to waterworks and an electric lighting station, called in Herr von Miller to carry out the electrical part of the work. The power station at Schöngeising, 4½ miles off, contains at present two knop-turbines driving on to a common shafting through bevel gear; there is room and sufficient water for a third turbine when required, making in all 180 H.P. From the countershaft are belt-driven two Brown-Boveri 2,600-volt alternators, and an exciter. Herr von Miller remarks that he chose the "single-phase alternate-current instead of the 'Drehstrom,' so much talked about of late, and first applied by myself at Heilbronn, because the latter requires three wires, and it is highly desirable, especially where we have overhead lines, to keep down the number of wires as much as possible." The turbines are governed by hand manipulation of the sluice-gates, and by an automatic governor which puts on the brake if the speed exceeds the normal.

The 2,600-volt current is carried to the outskirts of Bruck by 6mm. wires. A high-pressure ring main is carried right round the town (*see* Fig. 1), and to this a low-pressure (100 volt) network is connected by means of 10 oil-transformers placed at intervals in huts, having the external appearance of a sort of glorified letter-box (*see* Fig. 2). The low-pressure network has a total length of some four miles. When the high-pressure wires reach the limits of the town the height of the poles is increased, and where possible the wires are taken over the house-tops.

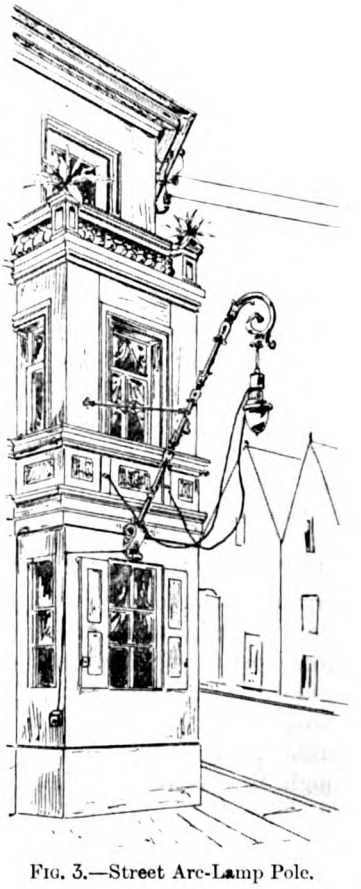

FIG. 3.—Street Arc-Lamp Pole.

With the two machines at present available, and allowing for a 17·5 per cent. loss in the line, transformers and low-pressure network, the station can supply current to some 2,600 simultaneously-burning 8 c.p. lamps or their equivalent, so that over 3,000 lamps may be connected up without fear of overloading. At present 1,500 glow lamps and seven arc lamps, distributed amongst 70 houses, are in use, in addition to 12 motors having a total of 18 H.P. These twelve motors assist at a varied assortment of operations; one helps to winnow corn, another assists the work of a soap-boiler, whilst a 5 H.P. motor has quadrupled the output of a carpenter's shop. The local agricultural club have on order a portable thrashing machine, which they intend to have driven by electricity. When we consider the price asked for the current and the method of charging, the extensive use of current (which has only been available for a few months) is no longer a matter for surprise. The total first cost of the present installation was £3,000, and Herr von Miller, being of opinion that it is more becoming to a municipality to encourage a general use of electricity than to make a "good thing out of it," decided to recommend the adoption of a very favourable tariff. Each consumer has to state the maximum current he is ever likely to require, and

Digitized by Google

an appropriate fuse having been inserted in the service main, he is charged 20s. per 16-c.p. lamp, or its equivalent, per annum. Taking private-house lights as likely to be burnt under these conditions, on an average 800 hours per annum, the cost of the 8 c.p. lamp-hour works out at 0·16d., whilst if we take a one-horse motor as the equivalent of 18 16-c.p. lamps, its cost for current will be £18 per year of $365 \times 24 = 8{,}760$ hours. As Herr von Miller points out, a method of charging of this kind is by far the best where water-power is concerned. It saves meters, with their unpleasant surprises for consumers at the end of each winter quarter; and since a river refuses to stop flowing until the sun sets, unless expensive dams and weirs are used, it may as well be made use of, and by granting the lowest tariff compatible with a moderate profit and the payment of working expenses, interest, depreciation, and repairs, the employment of motive-power is encouraged, and water which would otherwise run to waste is utilised; the working expenses of the station being increased only by an inappreciable extra amount of wear and tear, and a little larger consumption of oil and waste.

The motors are worked off transformers, the sudden rush of current on starting being prevented by gradually switching in extra coils on the motor or secondary circuit. A large portion of the building and line work was carried out by local workmen, who, amongst other things, were responsible for the street arc lamp supports, which, as will be seen from Fig. 3, have the advantage over our London ones of originality, and of being out of the way, although it must be admitted they do not so very remotely resemble barbers' poles. It may be mentioned that the technical staff of the Fürstenfeld-Bruck municipal central lighting station consists of two turbine and dynamo tenders at Schongeising and a works manager at Bruck. No reserve of steam-power is provided at Schöngeising against periods of extraordinary low water, Herr von Miller being of opinion that the best, not to say the cheapest, reserve are the disused petroleum lamps and farthing dips. It may be mentioned in this connection that the Castle of zur Post at Bruck has a yearly lighting bill of £20, which is exactly the same as was formerly paid for less light from petroleum lamps.

PARLIAMENTARY INTELLIGENCE.

THE ELECTRIC POWERS PROTECTION CLAUSES.

The evidence before the Joint Committee was opened by Sir Courtenay Boyle, as reported in our last issue. In stating the case with great impartiality he displayed a much more intimate acquaintance, not only with the general conditions of electrical traction and telephony, but with the electrical details, than might be expected from the chief officer of so extensive and miscellaneous a department as the Board of Trade. Mr. Preece following, introduced perhaps rather too much pure science when he alluded to that which was "commonly called induction, but which was now explained to be due to the passage of electromagnetic waves through the ether which fills all space." On the other hand, he said that the earth currents spreading from the City and South London Railway over the neighbourhood "give rise to a great waste of energy." If the current were confined to the return conductor and the tube, the resistance would be higher than at present; so as far as expenditure of energy is concerned earth leakage is an advantage. A more serious mistake, fortunately detected and set right by Lord Russell was that these earth currents "extend as far as Norfolk." A few Leclanché cells can easily, and do indeed every day, give rise to currents which "extend as far as" from England to America, for the simple reason that there is an insulated wire to carry them; and if there were not they would not go. Considerable disturbance seems to have been wrought in many editorial minds by this bit of evidence. The *Evening Standard* thinks that the evidence given by Mr. Preece was "not a little awful"; and many other papers show signs of believing that the City and South London Railway sends electric currents *through the earth* "as far north as Walsham, in Norfolk." During the early sittings of the commission the "accidental" and the "intentional" use of the earth was frequently alluded to; the expressions were unfortunate and seemed to introduce ambiguity. The National Telephone Company made a very good case as to their extensive and cheap service, but the comparison between their charge for a "message" and the average charge by the Post Office for a telegram is quite illusory. If big differences are wanted, why not estimate the cost per word, making a special reduction for "Are you there?" and "Speak up, can't you?" The suggestion made by two witnesses of stopping the whole telephone system of Liverpool for five or six years if electrical traction were introduced there, was too absurd for such sensible men as the members of the committee. Lord Cross quickly disposed of it on the second occasion. Curious exaggerations were as common here in the evidence of the experts as they are in the Law Courts. Sir Frederick Bramwell estimated the extra cost of a metallic overhead return—a double trolly system, in fact, as at Cincinnati—as only 6 per cent. more than that of a single line. The Committee had the pleasure of gazing day after day, after this, at a large model of a junction on the double trolly system, an excellent object lesson on the complications and expense of the method. Another rather curious piece of evidence was introduced, apparently from the evidence given on the projected Clapham Junction and Paddington Railway, that a certain magnetometer was 70 times more sensitive than a certain microphone. Both instruments are well adapted to measure disturbances due to electric traction, but these disturbances are totally different, and are not comparable. Purely magnetic disturbances are of very little importance, and magnetic disturbances arising from stray currents are not very reliable for use in measuring the currents. Mr. Swinburne and Mr. Crompton were the only two witnesses who gave scientific evidence for the defence. Mr. Bennett, the only witness who was subjected to unpleasant cross-examination, gave evidence to rebutt that offered by the Telephone Company. After the evidence for the traction companies was closed by Gen. Webber, the electrical engineer to the Corporation of Blackpool gave some interesting information. The negative pole of the tramway has been put to earth for some time, and no trace of electrolysis has been found. After this an interesting group of experts in democracy were called: the town clerk of Walsall, the Mayor of Leeds, the Mayor of Salford, and a member of the Manchester City Council. These were unanimous, and expressed their opinions most emphatically, that telephones were all very well, they did not want to harm them, but they were of no importance compared to cheap traction, and they would readily abandon the telephones rather than impede the development of electrical traction. We have commented elsewhere on the evidence of Major Cardew and of Prof. Dewar. It may be said to only break the ground of a new and important inquiry which will no doubt be carried on by Major Cardew's investigations and tests. Sir Frederick Bramwell, appearing as he did for the gas and water companies, had no difficulty in arguing that insulated returns were the only remedy. A rather more easy line to adopt would be to say that electrical traction should be prohibited.

WEDNESDAY, JUNE 21, 1893.

Mr. D. SINCLAIR (Engineer-in-Chief to the National Telephone Company), examined by Mr. MOULTON, said that he had superintended the construction of the entire telephone system of Glasgow, which had 4,000 subscribers. The subscribers' wires there were on the single-wire system, and the trunk communication on the duplicate system. That arrangement had worked very well. Owing to the peculiar position of London, the main service there was not so good as in other towns, principally because London being such a large town it was, telephonically speaking, a series of large towns connected together; but, comparing it with Berlin and Paris, he should say that the service in London was better than in Paris and equally good with Berlin.

Mr. MOULTON: With regard to the duplicate system for subscribers' lines, what objections do you see to that?

The WITNESS said that scientifically there was no objection. Scientifically, the metallic circuit was better than the single wire, but when it became a commercial problem how to produce so much commercial result by a certain process, they had to take into consideration whether they could do it well enough with a single wire, or practically as well, as with a double wire. In many cases where permission would be given to carry a small number of wires, it would be withheld if the number were doubled, but if they had to duplicate their lines in any town the cost of the switchboards would be very great in addition. If they had 4,000 lines in an exchange, that meant that they must bring 4,000 contact points within the

Digitized by Google

reach of an operator, which was confined to so many feet; therefore, if they had a greater number of lines into that place than the operator could reach to or along, then they made it impossible for the operator to work the switchboard. For each metallic circuit they would have to provide two jacks or points of connection, and if that was carried out to a large extent the space to which the operator would have to reach became so extended that they could not reach the top loft.

Mr. MOULTON: If any change was ordered, would it take any considerable time to make it?—Taking the town of Liverpool, there were 3,500 wires. If they had to metallic those overhead, the standards which carried the present wires would not be sufficient, so that it would mean sweeping down the entire system and building up a new system to carry twice as many wires. Inasmuch as it was impossible to work an exchange partly on the single and partly on the double on any large scale, they would have to make the change all at once.

The CHAIRMAN asked how it was done in London, because evidence had been given that in London the system was being exchanged at the present moment.

The WITNESS said that in London they were doing substantially what he had suggested. They were providing extra wires, so as to make the metallic circuit, but, with a few solitary exceptions, they were not yet put into operation, as they could not work the mixed system.

Mr. MOULTON: Practically these new wires will be idle until you can make the exchange?—That is so, and undoubtedly some will lie idle for years.

At this point Dr. HOPKINSON was recalled, by the request of the Chairman, to explain the actual action of electricity when it was once set to work in the telephones, and explained the manner in which the current was transmitted from the battery to the receiving instrument. Asked to explain exactly what he meant by the terms "current" and "transmission," he said he did not think anyone knew exactly what they were. He did not think anyone knew whether the energy which was transmitted for an electric current passed along the wire or through the medium which surrounded the wire. As to the electrolytic action, it had been found in America that pipes had been actually eaten through in consequence of it.

Mr. SINCLAIR'S evidence was then proceeded with, and in reply to Mr. Cripps, he said that at Glasgow at the present time, to a limited extent, they used the same exchange for metallic and earth returns. At Stockholm there was very considerable difficulty in working some telephones on one system and some on another. While in the case of the National Telephone Company *v.* Graff Baker he had said that the earth returns were capable of being worked in connection with the metallic returns, it was a question of degree. Up to 5 or 10 per cent. they could very well be worked together, but he understood they were now providing metallic switchboards at Stockholm, which bore out what he so strongly insisted upon, that when it became necessary to metallic the circuits, it became necessary to metallic the circuit all round. Asked whether the difficulty of reaching over the switchboard could not be met by having additional operators, he said the best and only system, which was used in all large exchanges, was to have only one operator.

The CHAIRMAN: I understand what you mean is this, you have a great number of operators, but each one of those operators is so placed that he or she can work every wire that comes into the place?—The Witness said that was exactly it. The largest exchange he had ever seen actually operated was 6,000, on the multiple system, so that they could imagine what it was, that the operator had 22in. or 23in. to sit in, and within her reach they had to bring the connection for 6,000 lines. The operator on the other side had also to reach 6,000 lines, though, of course, they borrowed from each other to some extent.

Mr. CRIPPS: Why should there be greater difficulty on the metallic system than on the earth system of one operator reaching all the points of contact? The Witness said that he did not contend that there would be greater difficulty, but the difficulty came in when they had a mixture of both. The reason greater space would be taken up was because they could not put 40 into a space which was made for 20.

By Mr. BALFOUR BROWNE: He did not agree with what Mr. Forbes (the Chairman of the National Company) said before the Telegraphs Committee, that in London, Liverpool, or crowded areas, the metallic circuit was absolutely necessary.

By Lord RUSSELL: A continuance of the present system of telephonic communication debarred any increase of electric traction.

By Mr. MOLLOY: He would not like to say that there was no leakage in the return current. It all depended upon the local conditions. If it was a good conductor from end to end, and there was less resistance than in the earth, there would be no leakage. What would be an absolute cure in one soil would be death to the telephone in a different soil. Under certain conditions there would less resistance in using a tube as the earth return than if the earth alone were used, but it depended largely on the nature of the earth. If the earth subsoil were solid clay, then that was the best condition. The tube used in the South London Railway was always in contact with the earth, and was practically an earth return. The leakage or induction used by that earth return had affected the telephonic system slightly from time to time, and now and again the result was serious but they were too busy to pay any attention to it, unless it became so serious as to interfere with the subscribers' use of the lines.

By Mr. FORWOOD: No legislation was required to give them wayleaves over houses, as they were private property. If legislation gave them rights over the roads, it would immensely facilitate telephonic expansion in London and other large places, and be a benefit to the public, the subscribers, and everybody all round. The tendency of having such legislation would be to cause the wires to be put underground. The first cost of a double set of wires underground would not be less than overhead, but the cost of maintenance would be less, and they would always know where they were and what they were doing.

Sir FREDERICK BRAMWELL, examined by Mr. WALLACE, believed that the exercise of the telephonic industry was absolutely without injury to any other industry of any kind, as the electrical currents were so extremely small. Having described the system of working the electrical cars at Leeds, Sir Frederick proceeded to say that the disturbance to the working of the telephones caused by the tramway was intolerable. In the Exchange, when the cars were at work, they lost as many words as they heard. He did not see why the traction companies should be placed in any better position than the electric lighting companies. There were no mechanical difficulties in the way of their having insulated returns. It could only be a question of expense, and that expense, he believed, compared with the whole cost of the line, was an extremely small percentage, and compared with the cost of duplicating the telephones, he should say it was not to be regarded. He thought he ought to tell the Committee that he was a telephone shareholder, and also an electric light shareholder.

Mr. BALFOUR BROWNE: But you have no tramway shares?—No tramway shares.

By Mr. BALFOUR BROWNE: Although he could tell how the metallic current arrangement could be done he could not tell where it had been done. At Leeds the disturbance was due to the induction or leakage or both, but he could not give any idea as to the amount of leakage taking place. He could give it in terms of annoyance, but not in amperes and volts.

By Mr. CRIPPS: Motive power was supplied by the electric lighting companies to a very slight extent. If the private telephone companies were treated in the same way as the official Post Office they would have all the protection that they wanted.

Mr. CRIPPS: Then you want the Telephone Company to have the same control over the electric traction companies that the Post Office and the Board of Trade have under the Electric Lighting Acts?

The WITNESS said he wanted the same in effect, but he did not know that they wanted it done in exactly the same way. The telephone companies were the agents of the Post Office, and paid 10 per cent. of the gross receipts, and he thought they therefore should be equally protected. They were a large public company doing a public service, and also endeavouring to make a dividend for their shareholders; and he did not think the latter point was inconsistent with their having proper protection.

Lord ROSSE: Have you formed any estimate of the extra cost which would be necessary in case of the tramways to give a metallic return?

The WITNESS said he had not figures before him, but he had formed a general estimate in this way: supposing they adhered to the overhead system, as in Leeds, to have a return overhead wire as well as an outgoing overhead wire, it was obvious that the extra cost was nothing but that wire. The outgoing wire at Leeds was $\frac{4}{10}$in. in diameter; that was not a very serious thing, because they had the whole structure ready to their hand to carry it. Taking the total expenditure on the tramway lines, with buildings, cars, and everything of the kind, he was quite certain that the extra cost of a metallic return could only be a very small percentage of the whole outlay—he should think it would be about 6 per cent. If the circuiting were doubled, the pressure or tension would be doubled.

Major DARWIN: I think you express a strong opinion in favour of the underground system of return wires in preference to the overhead system for tramways?—Yes.

Do you feel that just as strongly for country districts as for town districts?—Witness stated that he did not. Assuming the Telephone Company were told that if they wanted protection they must make it for themselves by doubling the metallic circuit; assuming also that the tramway companies were told, "You may send your current to earth"; assuming, then, that under those circumstances the inevitable accident occurred to the telephonic communication, and they went to earth by misadventure, then they were not protected from what was being done by the tramway companies.

By Lord ROSSE: For telephone purposes an overhead wire was much better than an underground one.

Mr. W. H. WINTERBOTHAM (Solicitor to the National Telephone Company) was examined by Mr. PEMBER as to the legal and Parliamentary controversies which had taken place with regard to the Company's position. As early as 1884 various Provisional Orders contained powers to tramway companies to use electricity, but as electrical traction was not a practical matter till within the last four or five years, they did not take any notice of it. In 1889, however, considerable strides having taken place in electrical knowledge, the question of electrical disturbance of the telephone lines was brought to their attention, and thereupon they took action to have protective clauses in the various Bills and Provisional Orders before Parliament. The Witness described the contests that arose during successive years, which led up to the more general adoption of the Plymouth clause, and out of 52 Bills or Provisional Orders which they had had to do with, the Plymouth clause had been inserted in 38, while others contained more or less stringent clauses.

By Mr. BALFOUR BROWNE: They were told that 200,000,000 messages were sent in a year, but he did not know that the number of people who travelled on tramways in the metropolis alone was three or four times that number. He agreed that anything that would interfere with electric traction would be a serious matter to the public.

Mr. FORBES (Chairman of the National Telephone Company) was then called. In reply to Mr. PEMBER, he said that the proposition that had been put forward was that it was impossible to conduct the telephonic system efficiently without a metallic circuit, and therefore the Company in their own interest and in pursuance of their duty to the public, were bound to use the metallic circuit; moreover, it was contended that great harm would then be done them by somebody else using the earth. To meet that argument he would submit several considerations. One was this: How much of the telephoning of this country, and of any other, was done on the metallic circuit? They were doing in this country 95 per cent. of the business on the earth-current or single-wire principle, and out of London and some other large centres they were doing their work efficiently

Digitized by Google

and their subscribers, as far as they were aware, took into consideration the conditions under which the system had been developed. They knew, as a matter of fact, that from year to year complaints were being removed. He found that in certain places where the Post Office competed with them, despite the *prestige* attaching to a great public department, and despite the fact that the Post Office used a metallic circuit, whereas they themselves used the single-wire system, as a matter of fact their business progressed from year to year, and that of the Post Office remained stationary or diminished. That was tolerably fair ground for assuming that their system was the better of the two. He then gave statistics relating to the competition between the National Telephone Company and the General Post Office. These statistics, he said, were his answer to the suggestion that they could not conduct their business with such efficiency as to meet the public want unless they adopted the metallic circuit. He asked how they were to get their money back if they were obliged to apply the metallic circuit throughout their system; they were in possession of their licence for eighteen years and a-half, they had already spent a sum approaching to five millions of money, and they had got to get it back within that period. They certainly did not feel inclined to expend another million or a million and a-half for a mere fancy. He could not find any other reason for their remarkable development, except that the system which was thus proved to be an effective one was really the best system, and certainly it was the most economical. Whether they were expending State money, or private money, it was equally useless to spend it on what was not wanted. It appeared from the balance-sheet that the capital of the Company was £4,000,000, of which up to date they had spent £3,371,000 The income for 1892 was £463 741, or £100,000 more than in the previous year. The Post Office royalties were £54,000 or £55,000, and the dividend paid was 6 per cent. The Post Office had recently enunciated in a Treasury minute that they did not intend to grant new licences except under certain conditions, and he thought he had ascertained that they did not intend to grant them for any period longer than the extent of the National Company's licence, so he supposed it meant that at that time if the Government did not before exercise the power which they had of buying the telephones, they would have to restore them. Mr. Lamb, on behalf of the Post Office, had estimated the value of the Company's undertaking as it stood at the end of ten years at £1,000,000. If that were anything like true where was the difference to be got between £1,000,000 then and £5,000,000 now? It must be got out of the business. That was not encouraging to induce them to spend any more millions or hundreds of thousands of pounds, and as the years grew less it would militate against the expansion of the telephone business. He hoped that would impress the Committee with the extreme caution that the Company must exercise in doing useless things. If the common law right according to the Kekewich judgment was taken away by the action of Parliament giving unlimited powers to other bodies to put into the earth such a volume of current as destroyed the Company's business, and they were driven to spend a large sum of money in providing metallic returns, which were not wanted but for that, it would be a great hardship.

By Lord CLIFFORD: The objection to the underground system in London was that they could not get under the streets. They were at the mercy of every owner of property, some of whom would not let wires be placed over an entire estate, so that instead of going direct with a number of wires between two points, they had to find their way from one street to another, which caused a multiplication of exchanges. If they had power in London to use the streets as the Post Office or the gas and water companies use them, they could give an infinitely better service for London, because they could diminish the number of exchanges.

By Mr. BRUNNER: It had been thrown in the teeth of the National Company that they had bought up all the other companies. The 13 companies that had been bought had been bought up upon the very rational ground that if a telephone was to be conducted with economy and efficiency there must be some uniform plan of charge and control. To have 13 companies competing with them, one having its foot in one part of the country and another in another, would be as bad as the Irish railways.

Mr. PEMBER stated that that was all the evidence that he proposed to call on behalf of the National Telephone Company, and the case of the Associated Railways was then entered upon.

Mr. ASPINALL (Chief Mechanical Engineer to the Lancashire and Yorkshire Railway Company), examined by Mr. MOON, said that along the line of railway they had six different classes of wires, namely, block instrument wires, telephone wires, single repeater wires, Post Office wires (which they were asked to maintain for the Post Office), wires of their own for telegraphic purposes, and wires for sundry purposes connected with telephones for indicating purposes. Having described the purpose for and the manner which the various wires were used, he said that in August, 1891, they found that their instruments connected with the wires were being disturbed by the working of the Blackpool tramways, so that a line was indicated as clear when it was not clear, and when other trains were in the station. They had had disturbances before then, but had not been able to satisfy themselves that it was due to the action of the electric tramway until then. They found that while the disturbance continued throughout the day, it absolutely ceased when the tramway was not at work. The Railway Company considered that it was absolutely essential that they should have protective clauses given to them such as had been given by the Bolton Tramway Company. The clauses in the first instance provided that the Corporation should construct and maintain their electric circuit so as to prevent leakage and so forth. Before beginning to make their works they were to give notice to the Railway Company as to the nature of the works to be constructed, and the sort of current they intended to use; and the Railway Company were to make such requirements as they thought reasonable. By one of the clauses the Railway Company were to start at once and protect themselves as far as they thought necessary, the cost of doing so to be charged against the Corporation with reference to an arbitrator appointed by the Board of Trade, who would say whether what had been done was necessary, and whether the cost had been reasonable. The cost of doubling the wires on the Lancashire and Yorkshire system, so as to provide a metallic return, including the Post Office wires, would be £48,000, while the extra cost of maintenance, based upon the estimate which the Post Office already paid to them per mile for maintenance, would be £7.700 a year. Capitalising the maintenance charge at 33¼ years' purchase, and adding it to the cost of duplication, would represent to the Railway Company an expenditure of £305,000.

By Mr. BALFOUR BROWNE: Electric traction would affect them wherever electric tramways were started, and looking at the list which had been put in by Sir Courtenay Boyle, it showed so large a number of towns which were entitled to use electric power which were on their line that it alarmed them. They had such an intricate system of railway, and so many thousands of miles of wire, that they were really afraid of that system. Even with the expenditure of £48,000, they would not get absolute protection unless the tramway companies duplicated their circuit so as to prevent the possibility of leakage. Their signals had been altered by natural electricity during thunderstorms.

Mr. FLETCHER (Principal Assistant Electrical Engineer to the London and North-Western Railway) examined by Mr. MOULTON, described disturbances caused by electric traction employed by the South Staffordshire Tramways Company at Walsall. In order to protect their wires against the disturbance caused by the tramways, they had adopted the use of mechanical guards in addition to insulation, by which the evil had been cured.

By Mr. BALFOUR BROWNE: In order to do any injury to water-pipes there must be a difference of potential between the rail and the water-pipe; whether injury was done to the pipe depended upon whether the pole was negative or positive. The Railway Company had put down metallic returns in particular cases to avoid disturbance, in one case using a current up to about three amperes, and it was for the better working of that circuit to reduce the resistance.

The Committee then adjourned.

THURSDAY, JUNE 22ND.

Before proceeding with the evidence to-day, the Committee made an inspection of the National Telephone Company's exchange at East India-avenue, E.C., and at Oxford-court, E.C., and on their return to the committee-room the following witnesses were examined:—

Mr. WM. EDWARD LANGDON (Superintendent of the Telegraphic Department of the Midland Railway) examined by Mr. MOON, said that the signals of the Midland Company had also been affected by the operations of the South Staffordshire Tramways Company at Walsall to a distance as great as 3 miles 8 chains from the point where the tramway crossed the railway. The Midland Company ran through 32 of the 115 towns included in Sir Courtenay Boyle's list. In his opinion the only method to render the railway working safe was that such high currents as those used by the tramway companies should be entirely dissociated from the earth. Even if the railways protected themselves as far as they could by adopting metallic returns for their wires, that would not be sufficient protection unless they could ensure the insulation being always in a perfect condition. If they insulated the high currents from the earth in the first instance, and then insulated their own circuits from the earth in the second instance, then if anything went wrong with the high-current system they had another string to their bow. If they only duplicated their own wires, then if anything went wrong with their own wires the danger still existed. At Walsall he had duplicated each wire that was affected. He did not think that a single return being afforded for a number of wires would be at all sufficient. He would very much prefer giving each wire its own metallic circuit. He produced a block instrument, and explained its working to the Committee, stating that the Midland Company had 4,000 of them in use, and that the currents at Walsall affected the instrument so much as to carry the needle over to one side entirely. He considered that the Bolton clauses were the minimum that would be sufficient to protect the railway companies. The railway companies had no desire to impede electric traction; they would rather foster it than otherwise, and all that they sought was protection for the public traffic. No one had the right of monopoly of the earth: as telephone and telegraphic companies had the right to use the earth, and had not been dispossessed of it, those heavy currents if allowed to invade the earth would, of course, monopolise it, and would drive out all others that had connection with it.

Mr. HAMILTON: Supposing the effect of the Bolton clauses is to kill the tramways, have you no intermediate suggestion to make to the Committee between the death of the tramways and your clause?

The WITNESS replied that with him it was a question of public safety, and he could not depart from that position.

By Mr. WALLACE: The Company had 16,000 miles of wire, and he put the cost of duplicating one third of that down at £18,000. The additional cost for maintenance of the duplicated wires when capitalised would be £57,000.

By Mr. MOLLOY: The most effectual method of securing safety, as far as safety could be obtained, was to be found in the adoption of the metallic circuit, both for the tramways and for the railways. If it were only adopted by one or the other there would always be some danger from leakage, and they would only get half the protection. Dissociation from the earth on both sides was the only solution of the difficulty. As the question had been raised as to electrolysis, he desired to hand to the Committee an article which appeared in *The Electrician* on June 16th, 1893, on p. 172. This article had been written as to its effect on American railways.

Mr. SPAGNOLETTI (Electrical Engineer to the Great Western Railway Company) said that he had considered the best means of securing the safety of the public travelling on the railways in the event of tramway com

Digitized by Google

panies using high currents for the purposes of traction, and was of opinion that the best system was that of insulated conductors for the incoming and outgoing currents. They might make some provision which would last for a time, but in order to have certainty the returns for the tramways must be insulated. If railway signals were insulated it would make it more sure, but that alone would not be sufficient to secure safety unless the tramway companies also adopted metallic returns.

By Mr. WALLACE: Electric lighting currents were very similar to those used for traction. He had experienced disturbance on the District Railway in October last which affected the whole of the working of the system between St. James's Park and Sloane-square, when it was found that the generating station of the Westminster Electric Supply Corporation had short-circuited. It would not affect the railways unless there was an accidental breakdown of that kind. Whether tramway companies should be put under the same restrictions as the electric light companies depended on the construction of the line.

By Lord ROSSE: The segments of the tube in the South London Railway were all bolted together, and there was a layer of cement between the earth and the segment of the tunnel.

By Major DARWIN: The electric light machinery at Westminster was some hundreds of yards from the point where the disturbance was felt on the railway. The whole line was deranged between St. James's Park and Sloane-square; but beyond that there was no disturbance to interfere with business. That showed that the area of disturbance extended over some hundreds of yards.

This closed the case for the railway companies.

The CHAIRMAN said that when the evidence was closed on all sides, and after any evidence had been taken which the Committee wished to call, he hoped that counsel, in addressing the Committee, would turn their attention to the particular points which were actually referred to the Committeee and specially the terms of the clause that should be introduced.

Mr. JAMES SWINBURNE was then examined by Mr. CRIPPS on behalf of the electric traction companies. He said that he was Managing Director of Swinburne and Co. (Limited), and had been engaged in electrical work since 1881. He had given special attention to the action of electrical tramways and railways on telephones and telegraphs. He regarded the telephone as a most sensitive electrical instrument. Though the source of the disturbance was reduced very considerably it did not reduce the disturbance in the telephone to the same proportion.

Mr. CRIPPS: What is your view of what is known?—He (the witness) looked upon the single-wire system in telephonic communication shortly as a cheap and bad system; and he attributed all the difficulties in talking to the single wire and earth or water pipe return. The telegraph was not so easy to disturb as the telephone. For telegraphs the earth return was used, and it was also used in one sense for telephones, but that was rather a technical use of the word "earth," because, as a matter of fact, nearly all the telephones used water pipes as returns, which he considered made them more sensitive to external currents. The tramways had complete returns provided by their rails, and as to insulation, they could not insulate the rails because they wanted to make contact with them from point to point. Therefore, it necessitated the use of bare conductors. If the naked conductor is in a culvert, it must be below the level of the road; there was a slot which opened into the road and they had every possible means of allowing dirt and dust to get in because the conductor must be exposed all along inside the slot in order that the collecting brushes may reach it. They thereby had to keep the uncovered conductor miles long exposed to all that in the very worst position and in an ungetatable place. Water, and especially dirty water, was a conductor of electricity, and when that got on to the insulators and made contact with the ground the naked conductor was no longer insulated.

Mr. CRIPPS: It has been suggested that the water difficulty could be got over by drainage, and that the other difficulties were not such real difficulties as you are now suggesting.

The WITNESS said it was obvious that if the drainage system were perfect, they could prevent the water filling the culvert to such an extent that it would touch the wires; but even with the best drainage they could not drain away the damp, and the damp would cause injury. Of course, those were all matters of degree; but he thought, from a practical engineering point of view, it was impossible to practically insulate those things. That had been the experience in America. In America it was found, as at Leeds, that it interfered with the telephones, and the solution there was very simple: the authorities came to the conclusion that the roads were meant for traction and not for talking through. The double-trolly system would be difficult, so far as insulation was concerned, though not so difficult as the insulation of the double system underground. From a commercial point of view, it was not a practicable system. There was not only the difficuly of insulation, but the extra complication and unsightliness, and the great difficulty of managing the connection of the double overhead current. He regarded the single-trolly system as the most workable system for traction purposes. Referring to the Buda-Pesth system, he said that was only the beginning of a tramway system. It was only a few miles in length, with but few crossings, and was no example at all of what would be done if they had to put down a complicated urban system of tramways. Nine-tenths of the difficulty came in when they had branch lines, because the crossings of the wires and conductors had to be arranged underground in such a way that the tramway car should not have any short circuits. He did not think the problem had ever been solved. As far as he knew, the only way in which it had been done was by allowing gaps where the car was going straight along; but it would be impossible to work the system in a place like London. He did not think it would be possible to make the insulation so good as that it would not disturb telephones, and, in some degree, disturb also the railway people. If there were a clause that any interference with telephonic work would render them liable to an injunction, no engineer would proceed to put up a traction system. In addition to the difficulty from leakage, there was also the difficulty of induction, and the latter he considered generally the more important cause of disturbance. In the Leeds case, he agreed with Dr. Hopkinson that induction was a greater disturbing factor than leakage. Induction would take place with the most perfect insulation.

Mr. CRIPPS: Lord Kelvin told us that by certain alterations in the trolly contacts the difficulty might be met to a certain extent. You have made experiments, have you not, on that basis?

The WITNESS said that at Leeds he had an experiment made to find out whether that was so or not. A long flexible tube was taken from the car to the overhead conductor, so as to dispense with the trolly wire altogether, and another long flexible tube was taken to the rails at the other end of the motors. They ran the motor backward and forwards, and found that there was no appreciable lessening of the disturbance of the telephones. As to the question of expense to the Telephone Company in providing a metallic circuit, he had made no estimate, but he did not think it would be very great. It would not be necessary to double all the wires on an exchange because some were disturbed; if those that were specially affected by the traction currents were provided with a metallic circuit that would deal with the difficulty. He did not consider that it would be necessary to alter the switchboards in order to have a metallic-return system. As to the railway signalling, it would not be very expensive for the signals to be protected by a metallic return; one return for each signal-box would be sufficient. Apart from the question of traction currents, he had no doubt the telephone companies would be driven to adopt the metallic-return system. The National Telephone Company's licence would soon be out; there would be other competing companies who would compete with the National Company with a lower price or better service, or both. He had had occasion to investigate the disturbances to the telephones at Bournemouth caused by the electric light operations through the use of alternate currents. He could hear the hum in the telephone, but though the disturbance was very annoying, he could talk through it.

Mr. PEMBER: What system would you propose for London?—I submit that in considering the case of London, not only the systems at present in use must be looked at, but also those which may come forward in the next few years. A great many engineers were contemplating the use of surface conductors, made alive, as it were, by the car going over them, when it could collect current from them, and directly they passed over them they would be dead pieces of iron. Such a system as that may be the only system we can use in London, but that would require to be connected with the earth.

Has any such system as you are suggesting ever been at work?—Not commercially; it has been tried.

Then if that is the fact it is hardly fair to say that our clauses have stopped electric traction being worked in London, is it?—I do not think your clauses have been the cause. I would introduce the overhead system wherever the people would stand it; it is simply a question between the alleged beauty of the streets against tramway conveniences. It must be remembered that though the telephone wires are often a long distance away from the disturbing cause, the water pipes are frequently laid down along the streets, and if the companies got their connection through the water pipes the disturbance would be communicated.

Mr. POPE: You spoke of the roads being made for traction and not for talking; what did you mean by that?—I meant that to be my summing up. All the circumstances of the case should be taken into account. I did not mean to advocate any such extreme views as that the road might not be taken up to lay down water pipes, although that might impede the traffic.

With regard to gas and water pipes I understand you to say that the ordinary practice is to connect the telephone wire with the water pipe in a house, which, of course, is connected with the main of the water company?—Yes, that is the practice; I do not know whether the water companies ask for way-leave.

With regard to your companies the case is somewhat different. I believe you gave us the advantage of your assistance in the discussion of the Electric Lighting Orders for the obtaining of clauses for the protection of the gas companies; there it was decided that whenever any electric line may be laid down crossing, or liable to touch, gas mains, pipes, or services the conductor carrying the electric current shall be effectively insulated in a manner approved by the Board of Trade, and that the undertakers should not, except with the consent of the gas companies, lay down any electric lines so as to come into contact with any mains or pipes, nor employ any mains or pipes of the gas companies as conductors for the purpose of completing the electric circuit, or for the conveyance of electric currents. Does not that apply to this case?—As a matter of fact gas does get out of the gas pipes, and there is a possibility of leakage in the case of a culvert. If there was a possibility of the electric current eating away the gas-pipes it would be only fair that the gas companies should have protection, but I did not think that would happen. It would not be likely to happen with a properly arranged system.

Mr. CRIPPS: So far as traction companies are concerned, would you get uniform currents or not?—You do not get uniform currents, you get direct currents, but it is the variation of these currents which causes the disturbance.

Do you think the danger of electrolytic action in regard to the gas mains could be provided against?—Certainly.

Whether you have a metallic return non-insulated or a ground return?—That is the same thing. The simplest way is to have the ground return as the negative conductor, and with the Gas Company's permission I should like to make them the negative pole.

By Mr. FORWOOD: He had studied the tramway system in America a good deal, but had not seen the Boston system. He believed it was entirely overhead. At one time they started a culvert system, he believed, but had given it up. Asked if there was any culvert system besides Buda-Pesth, witness mentioned Blackpool, where there was a short line along the esplanade.

Digitized by Google

By Mr. MOLLOY: As a matter of fact any electrolysis would only prevent the pipes from rusting. An ampere would eat away about six or seven grains in an hour.

By Lord CLIFFORD OF CHUDLEIGH: Theoretically it might be possible to get over the difficulty of passing points, as at Buda Pesth, by storage; in practice the increase of weight of the accumulators to the cars would be a very serious drawback.

Mr. R. E. CROMPTON was then called. In reply to Mr. GRAHAM, he stated his firm, in connection with several other firms, had been asked by the Glasgow Corporation to carry out an undertaking on the understanding that they should take over the responsibility of complying with the protective clauses introduced into their Provisional Order, and they found themselves utterly unable to take the responsibility on their shoulders. He spent a long time in trying to find out if it were possible to devise means to so arrange their plant that they should not affect the telephone lines, and the result of his investigations was that he was reluctantly obliged to write to the Glasgow Corporation, and inform them that they could not undertake the responsibility. He found that there was no known means in the world of doing what they were asked.

That is to say, it is practically impossible to insulate electric tramways in such a way as not to interfere with telephones?—I found it was impossible so to insulate as to make it quite certain that we should not interfere with telephones. Double overhead conductors would be out of the question in this country; any attempt to make a double overhead system was a waste of time, as he did not think it would be permitted. Single overhead conductors had been greatly objected to by local authorities. His intention was to attempt to perfect a system of underground insulated conductors; he had made inventions and taken out patents, but he regretted to say he had not been able to introduce them into any complicated system of lines. There were difficulties in the way of crossings, and so on, which were apparently easy to overcome until the details were considered, but the difficulty of working with two insulated conductors was so great as to be practically impossible with our present knowledge. The double insulated conductors would involve a number of blanks, or places where one of the conductors was stopped off, and the car would be without propelling power on those parts. He had been to Buda-Pesth and examined the tramway system there. It had been constructed regardless of expense, and was a magnificent piece of work, but at the same time, they had not attempted to deal with the difficulty of blanks. When a car stopped it was shouldered over the crossing, the guard putting his shoulder to it and shifting it over.

What do you consider will be the future mode of working tramways by electricity?—I think that a slot system will probably be used. It would be necessary to have the rails insulated so far as they could be, but he did not think they could completely insulate the rails under ordinary conditions.

Is it possible to insulate in such a way as to insure not interfering with the telephone?—In my opinion it is not possible. He should think only a microscopical current would pass to the gas pipes: the question of electrolysis due to leakage for continuous currents was one which had been enormously over-estimated and exaggerated. During the number of years they had been at work in London he had taken every means in his power to ascertain if they were actually doing the damage by electrolysis that it had been contended they would do, and he had never yet traced a case, provided the precaution were taken of connecting the proper pole of the generating system with the earth. They were allowed to connect any pole to the earth under the Board of Trade's rules at present, but on account of many of their conductors being in private houses, where there was always leakage, it was much easier to arrange that the bulk of the leakages should be on one side of the system, so that they could get the negative pole of the system nearest to the earth's potential; when that was carried out there was practically no attacking of the metallic pipes whatever. He believed that all the cases which had been returned had been due to current when other poles had been at earth's potential; under such circumstances they knew that accidents took place very rapidly. As a rule, in such a case, the insulation of the electric lighting mains suffered a good deal from leakage. They only discovered this by actual practice two or three years ago, and now that they had discovered it they had no longer any further trouble. He had a great many mains in London under his control, and he was convinced that the ordinary corrosive action of certain soils in London was infinitely in excess of any such action which took place from this source.

It has been suggested that as electric lighting companies can live under these clauses, therefore tramways can, what have you to say to that?—The cases are so very different that I cannot compare them. The electric lighting companies can show that their own mains are practically tight, and the leakage through them is so infinitesimal that it need not be considered. In the case of a tramway a large portion of the conductor must be exposed to be rubbed by the collector of the tramcar, and on that portion conducting matter, such as muddy water, or, what was worse, the shoddings of the rail, particles of iron mixed with mud, or nails, might fall, connecting it with the earth. There is nothing of that kind to be taken into consideration in the electric lighting system.

Mr. PEMBER: What has your experience of traction been?—I have only constructed one tramway, at Southend. It is two miles in length, and had paid its capital twice over, I believe. The system is a return by the rails, with one conductor. The line runs from the town to the end of the pier. I am aware that there is a tramway being constructed in the Isle of Man, but there is a difference between a tramway being constructed and working. I might say that it is a very simple line in the Isle of Man.

Are not the copper wires a little to one side of the slot at Buda-Pesth?—That was the first thing that occurred to me, but I saw that it did not answer. I got permission to go to the works, and saw one of the covers off. I could see where the mud was wiped each time by the rubbing contact. The tramway worked with a leakage, and did not answer so perfectly as they were given to understand.

The Committee then adjourned.

FRIDAY, JUNE 23RD.

Mr. CROMPTON was again called to give further evidence, and, in answer to Mr. GRAHAM, stated that there was no attempt made at present to get over the difficulty of the crossings at Buda-Pesth. Double ploughs had been tried on other tramways, but the extra complication involved was so great that they did not derive the advantage from them they expected. Two conductors in a conduit were very much more difficult to insulate than one. The space between the conductors had to be greatly augmented at Buda-Pesth. Such a culvert, although possible at Buda, where there were not many underground gas and water pipes, was absolutely out of the question in our cities, like London, Manchester, or Liverpool, and therefore the talk about that system being a possible system in England was, in his opinion, entirely useless.

By Mr. MOLLOY: It was practically impossible to carry on the traction system without allowing some leakage.

Earl RUSSELL: You say that the complication in the crossings would interfere very much with using a double slot; do you think to use one overhead wire insulated, and one underground return also insulated, combined trolly and plough system would work?—I have not worked out the problem; there are possibilities in it.

If it did work, it would do away with the difficulties about crossings?—Yes, apparently.

Mr. BENNETT was the next witness. In reply to Mr. CRIPPS, he said he had received an order from the House of Lords to give evidence, without which he should not have come. He had had 24 years' electrical experience, and 13 years' experience as a telephone engineer, and was at the present time general manager and electrician to the New Telephone Company (Limited). He was the inventor of the telephone translator, an instrument which made it possible to connect metallic or circuit-trunk lines by single wires without return. He had also invented the overhead house construction adopted by the National Telephone Company in Glasgow and other Scottish towns, which system was now being introduced into London.

What would be the difference between the cost of a new telephone exchange on the metallic-circuit system and the amount generally spent by the National Telephone Company on constructing single-wire exchanges?—A metallic-circuit exchange if it is not from the beginning exclusively for metallic circuits, and without any intention of putting up single wires in the ordinary way, would not cost appreciably more than a single-wire exchange with only one. The adoption of the metallic system enables the individual wires to be grouped closely together without any interference with the efficiency of the service, so that the wires may be put into cables, and a great many may be contained in a small diameter. The open wires which have to be used in a single-wire exchange have to be strung up by supports, each wire being kept at a distance which should not be less than 8in. or 9in. apart, 12in. being the preferable distance. Therefore, the space unoccupied by the wires on the single-wire exchange is necessarily much greater than if the wires are put into a cable.

Is it possible to put the wires into a cable?—It is possible for short distances, but there are practically defects in the method which weigh very enormously against it. If single wires are put into a cable they are necessarily brought very closely together, and the induction which takes place between wire and wire is greatly augmented, so that except on very short lengths the induction is very much greater between single wires if grouped in a cable than if strung separately overhead.

Is it your view that the cable can only be used effectively if you have a metallic return system?—Most decidedly. The cables do not occupy so much room on the roofs, as the wires are in a much smaller space, and require very much smaller supports, poles, and standards than open wires to the same number would. With underground wires the only practicable system would be the metallic-circuit return.

In your view would it be necessary to have an absolute duplication of every wire?—No. I should regard such a system as practically impossible. I should abandon all idea of exactly doubling the number of open wires, but I should replace the open wires to a very large extent by cables containing metallic circuits, these cables to be put by preference underground. The cables could be erected and not brought into use until they were needed, when they could replace an equal number of circuits upon a single wire. Instead of doubling every single wire it would be possible to use a few common return wires of high conductivity which would replace the earth at the subscribers' stations and also at the telephone exchange; such a method would not be so complete a one as the entire doubling of the single wires, but for all practical purposes in an old town where the single-wire system had been installed it would suffice, and that would not be nearly so expensive. The most perfect protection for the railway signals would consist in the absolute duplication of the wires working those signals, but the disturbance might be got rid of also in two other ways—first, by a common return wire, or, to avoid accidents, two separate return wires joined together might be used for a considerable number of railway instruments.

In cross-examination by Mr. PEMBER, the witness was closely pressed as to his connection with the New Telephone Company, and he refused to give information which he had received confidentially. He was also examined as to his alleged reluctance to give evidence.

Mr. ALEXANDER SIEMENS was the next witness. He stated that the exchanges at Johannesburg and Edinburgh were metallic returns, and so were the exchanges which the Government had put up in India. The exchanges in Australia were being changed into the metallic-circuit system because the telephones as soon as they multiplied interfered with each

Digitized by Google

other, apart from extraneous influences. This was done at great expense, but they could not have an efficient service without.

Mr. WALLACE: Should block instruments for railway purposes be insulated by metallic returns?—As a matter of fact the block signals are mostly already guarded against single-current impulses.

Does the making of metallic-circuit returns for telephones mean the doubling of all the wires?—Not necessarily, but if you want to get rid of induction as well you should double all the wires. In the Leeds case the chief difficulty to be dealt with was the difficulty from induction. He believed for telephonic purposes underground wires would take the place of overhead wires; the tendency in general was to get rid of overhead wires and put them underground.

Mr. J. H. GREATHEAD, C.E., was then examined. He said, in reply to Mr. GRAHAM, that he had for many years devoted his attention to traffic facilities in towns. He gave statistics with regard to the City and South London Railway. In consequence of complaints as to disturbances, he had a consultation in 1891 with Mr. Preece, and at his request made certain alterations. Since that time he believed there had been no disturbances of any importance. The cost of the Liverpool overhead line was £85,000 per mile.

Mr. F. JENNINGS PARSON, the next witness, stated that he was Chief Engineer of the Thomson-Houston International Electric Company, Paris. The double overhead system had been in use in Cincinnati in the United States for some time. It was satisfactory as far as it went, but it cost a great deal to install it and keep it up. In America, where there was a scattered population, they usually took a single-wire return for a group of houses. The effect of electrolytic action had been felt there, and it was sought to remove it by putting down a very much heavier return wire. In Boston, which had, perhaps, the largest tramway stations in the world, they found that the currents strayed so much as to produce more or less electrolytic action, and they were now putting down a wire of 18 diameter.

Mr. PEMBER: What other system besides the overhead would you suggest?—I would suggest brackets running along the side of the street.

Mr. S. SELLON was then called, and stated that the clauses seriously impeded the development of electric traction.

Major-General WEBBER was asked which was the better system, the overhead or the underground. He said that wherever conductors were more than seven or eight in number he should place them underground. With that number, or less, he thought they should be overhead. If overhead wires were used they were bound to have a metallic-circuit system. In the case of lines which might be put overhead, having seven or eight conductors, one strong metallic return would be sufficient, and therefore the duplication of the line, would be entirely confined to the small branch lines running to the houses of subscribers, the average length of which, compared with the others, might be taken as one sixteenth to a mile. The relative cost of a single overhead wire and of a single underground wire had been greatly exaggerated. £11 per mile was a well-recognised figure for an overhead wire, where there were existing posts. £130 per mile would provide a tube into which a considerable number of wires might be drawn. When the ground was taken up for one such tube a number of tubes might be laid, and into each of these a number of wires could be drawn. It would be found that the cost of an overhead wire was little, if anything, less than that of an underground wire.

This closed the evidence for the traction companies, and witnesses were then called on behalf of the Municipal Corporations of England and Scotland.

Mr. HESKETH (Electrical Engineer to the Corporation of Blackpool and General Manager of the Electric Tramways at Blackpool) said that with regard to the question of electrolytic action, he had had occasion to inquire into the subject. He had recently taken up all the main streets for the purpose of laying down electric lighting conduits, and had failed to discover any evidence of electrolysis. The connection was made to the water pipes, and was in operation when he went to Blackpool last August, and the effect of the precautions which they had taken was to prevent any electrolytic action. Being interested both in telephony and telegraphy, as well as electric traction, he had made frequent tests whether the working of the tramway produced material disturbance in the working of the telephones. He had never found interference from the tramways, but the interferences were due to the cross talk from telephone wire to telephone wire. He was about to modify the Blackpool tramway system to some extent by adopting a cast-iron conduit with a lid to it, so that the tram should only open the conduit at the time that it passed over it, and make contact with the conductor in the centre of the conduit. By that means he hoped to avoid trouble from the introduction of the dirt and water, which at present affected them very much. He thought it was most unnecessary that a tramway should be compelled to use insulated returns in the way described by the witnesses for the Telephone Company, and as an electrical tramway engineer he should decidedly protest against such being brought under his charge. The difficulties in the crossings and the return were great, especially in a conduit system. He attributed the inefficiency of the telephones to the earth-return system, and said that the Blackpool Corporation had been obliged to take the local exchange into their own hands and put down metallic returns. The Tramway carried over a million passengers last year, and he should deprecate anything to injure their successful working.

By Mr. POPE: The Corporation regarded the railways as of such importance that they could not but make all possible overtures to prevent interference in any reasonable manner, and they had given a clause undertaking to work the tramways so as not to interfere with the block signals. The railway companies were also to make some alterations in their own system, otherwise they would not have been able to accept the clauses.

Mr. JOHN COOPER (Town Clerk of Walsall) said that they had a system of tramways, 11 miles 5 chains in length, within the borough of Walsall, connecting Walsall with West Bromwich, Wednesbury, and Darlaston. The tramways were at first worked by steam; but owing to the annoyances from noise and smoke, they decided to adopt electricity. The results of the working had been highly satisfactory to the public the Corporation had been pleased with it, and there had been a large increase of traffic. There were 85 telephone subscribers, while over a million persons were carried on the tramways. The Corporation regarded electric traction as of greater importance to the community than the telephones they did not wish to do away with either; but if obliged to do away with one, would prefer to do away with the telephones. There had been a practical difficulty in the working of the telephones, though there had been a certain amount of roaring, but not sufficient to prevent communication. A number of the telephone wires were attached to public buildings in the town by licence of the Corporation, and the Corporation had given the Telephone Company warning that if they made any fuss about interference by the tramways, they would withdraw the licence.

Mr. YOUNG (General Manager of the Glasgow Corporation Tramways) said that the Corporation possessed 30 miles of tramways, which were constructed at a cost of £345,000, but they were at present leased to a Company, the term expiring in 1894, and the Corporation had made arrangements for working the lines themselves on the expiry of the lease. They had powers to work by electricity, and their act contained the National Telephone Company's clause. The Council had advertised for tenders for rendering the lines adaptable for electric working, and made it a condition of the contract that the contractor should be liable for any damage occurring within the meaning of the Telephone Companies' clause. The result was it was that though they had 11 offers to tender, none of the contractors would accept the responsibility of that clause. All those who tendered refused to indemnify the Corporation against the consequences which might fall on them under the telephone clause.

Alderman WARD (Mayor of Leeds) said that in that town they had 2½ miles of tramway worked by steam and horse-power in addition to the Roundhay Park line, a little over three miles in length, which was worked by electricity on the Thomson-Houston system, and let to Mr. Gray Baker. In the Corporation Bill now before Parliament they sought power to work the other 22 miles by electricity; the Bill was opposed by the Telephone Company, whose *locus* the Corporation disputed. The *locus* was allowed, and rather than have the Telephone Company's clause put on them the Corporation withdrew the clauses proposing electric working on the other tramways, as they thought they could afford to wait. But considered they ought to have power to work those lines by electricity when they came into the hands of the Corporation. Their experience of electric traction was most satisfactory; there was no portion of the lines that was so popular as that worked by electric traction. The feeling in Leeds was that there should be no clause introduced which would prevent the general adoption of electricity on the tramways.

Sir BERNHARD SAMUELSON: Do you object to the adoption of the Plymouth clause in particular, or to any clause?—The Witness said that when the matter was under consideration they were virtually asked to insert the Plymouth clause in their Bill, but they were not prepared at that time to accept any clause.

By the CHAIRMAN: He did not wish to hurt the Telephone Company in any way, as they rendered a public service. In Leeds the telephone companies were adopting the metallic return where there was any distance. If any plan were presented to the Corporation by which they could work the electric tramways without doing injury to the telephones they would be very glad to adopt it.

Mr. KEEVNEY (Mayor of Salford) said that over £90,000 had been spent upon 13 miles of tramway line in the borough, and under the Provisional Order they had power to use electricity. The lines were coupled up with the Manchester tramways, so that they formed one continuous system. This year they introduced a Provisional Order for the purpose of doubling a little bit, about 100 yards, of the tramways, but the National Telephone Company opposed them most unjustly, asking that their clause should apply not only to the piece proposed to be doubled but over the whole line. That he considered unreasonable, as they had previously obtained powers for electricity over the whole line. In consequence of that opposition they withdrew the Bill for this Session, but he added, "we shall have a go at it again." They had a right to use their own power, and did not want any one to interfere with them within their own boundary. Let the telephone companies follow their own pursuits but they must not come and block us, that is certain.

Mr. JAMES WILSON SUTTON (a Member of the Manchester City Council) said that as in future the telephones might have to be placed under the streets, he considered that it would be better public policy that they should be in the hands of the municipalities or that there should be a competitive State system. In Manchester they did not permit interference with the streets, either by gas or water companies, electric lighting companies, hydraulic companies, or anyone else; the Corporation did everything. The Manchester Corporation owned about 30 miles of tramways which were linked up with those of Salford and Oldham. They wanted to secure in the future the very best mode of traction which science could suggest, and it appeared to him that if they were debarred from using electric traction to serve the interests of a private company it would be a very serious matter. Comparatively few persons used the telephones, but millions of persons used the tramways, and if the two interests were in conflict, the Manchester people thought the public interest should be considered before the private interest. Any system of telephony which could be interfered with by electric traction must be an imperfect system.

By the CHAIRMAN: They did not want to do any harm to the telephone system at Manchester, they wanted to develop it, and deplored the fact that it was so imperfect. The Manchester Corporation would prefer to see the wires laid underground, but would give the right to break up the streets to no individual company.

The Committee then adjourned.

Digitized by Google

MONDAY, JUNE 25TH.

At the commencement of the proceedings the agents for the Corporations of Nottingham and Liverpool informed the Committee that though those bodies agreed with a great deal of the evidence which had been given by the Municipal Corporations of England and Scotland, they desired it not to be taken as agreeing to everything that had been said on their behalf.

Major CARDEW (Electrical Adviser to the Board of Trade) was called by the Committee as an independent witness, and stated that it had been his duty to make examination in various cases in which accidents had occurred. Since 1887 he had given a great deal of study to the question of electricity. Sir Courtenay Boyle had requested him to correct his evidence with regard to the accidents at Preston, which he had attributed to electrolytic action. That, at any rate in the witness's opinion, was not the case. He attributed those accidents to heat caused by the passage of the electric current between the iron culvert in which the electric light mains were contained and the gas service pipes which were injured. By the courtesy of the Preston Gas Company he was able to produce specimens of those service pipes which were cut out immediately after the accident. That which was the result of the accident in Wheatley-square on January 27th last had a hole eaten out of it where it was in contact with the culvert, and on January 25th the lead service pipe in Wheatley-square was melted.

The CHAIRMAN: What do you attribute that to?

The WITNESS said that he attributed it to an electric arc set up in the first place by imperfect contact between the culvert and gas-service pipe, and as the gas-service pipe melted away, the arc was established which caused the fusion, and which was due to the imperfect state of the works of the Electric Light Company. One side of the circuit had a temporary connection with earth, accidentally formed, and the other side of the circuit was accidentally brought into connection with the iron circuit enclosing the main. On February 24th a service pipe to a stationer's shop in Fishergate had three inches of it melted where it came in contact with the Electric Light Company's culvert. Those accidents were not due to electrolytic action, but to something much quicker, viz., heat produced by a current of electricity through them. The dry and sandy nature of the soil in Preston, in his opinion, had something to do with those accidents.

Mr. FORWOOD: Then the heat which was produced was due to faulty insulation of the mains inside the culvert?—That is true.

Earl RUSSELL: I understand that those are due to accident; if so, it would be impossible to prevent those by protective clauses.

The WITNESS said he did not think it was impossible to prevent accidents happening, although he did think the likelihood of serious accidents happening might be very greatly diminished by precautions which might be taken as a result of attention to regulations. He did not wish to bring anything in the way of accusation against the Electric Light Company, as they were but starting, but he thought under the circumstances, and the engineers of the Company would agree with him, sufficient care had not been taken before the accident. A long line of culvert, containing bare conductors, being allowed to come so near the bare unproducted gas pipes was an error of judgment, and was probably due to the hurried way in which the installation was carried out.

By Mr. MOLLOY: The electric conductors were strips of copper in the iron culvert, which was roughly half a cylinder with a flat top, and the electric light strips being held on insulators inside were separated from the culvert by 2in. or 3in. everywhere. But the connection was not made through any failure of contact between the strips and culvert, but was owing to defective arrangements in switching in some lamps for public lighting, and by that means the electric light conductor was brought into connection with the lamp post and the culvert, and thereby escaped to the gas pipe, which had previously been used for supplying the lamp.

By Sir BERNHARD SAMUELSON: Such accidents were certainly preventible. As far as his experience went he did not think it was usual to have lead gaspipes underground, but they were usually iron

By the CHAIRMAN: His attention had been drawn to several other cases of damage to water and gaspipes, and by tests which he had carried out he was enabled to prove that damage was caused by electrolytic action. He produced one of the pipes which was very much corroded throughout, but thought it better not to mention the name of the town in which the damage occurred. The difference of potential which he found on testing between the electric culvert, which was of the same character as the one in Preston, was 6 volts, which was quite enough to account for considerable electrolytic action. The pipe was full of water at the time, and the same current which was flowing through it and causing corrosion on the positive side must also have been causing corrosion on the negative side. On the subject of electrolytic action, he would like to mention the question of metallic connection between the negative terminal of the dynamo and the water mains in the case of dynamos. In the case of the Leeds Tramway and one or two other tramways, that connection was made by his suggestion, but it had never been the subject of any regulation, for one reason, that the Board of Trade was not empowered to make regulations on any water company. But considering the conditions that the current was being returned by uninsulated rails, and that there were water and gaspipes in the immediate neighbourhood, he considered it most essential that the Tramway Company should take all reasonable precaution to prevent damage to the pipes, and he suggested that a good way to do so would be to connect the negative terminal of their dynamo to the water main, the result of that being to raise the whole of the electric circuit in what is called potential positive to the water mains and the earth. If that were the case, any leakage crossing between the electric system, including the uninsulated rails, and the water pipes would tend to corrode the rails and to preserve the water pipe. That connection was made about a year and a-half ago, but he had never felt absolutely satisfied and certain in his own mind; he thought very few people were quite certain as regards what might happen with new developments of electricity. When visiting Leeds a year ago he discovered that the potential of the rails, as he had anticipated, was everywhere positive to the water pipes, and amounted to two volts at the extreme end. He could not find any sign of injury to them, although the road was opened in many places. As a year had since elapsed, he proposed to go down to Leeds again to see how that arrangement worked.

By Major DARWIN: In the case in which electrolysis had happened, it might have occurred inside as well as outside the pipe, but they would not be able to get at the inside. The soil in which the pipes were laid was wet and also salt. He handed into the Committee an interesting article* on the subject from a French paper, *L'Industrie Electrique*.

By Mr. MOLLOY: In the last case which he mentioned no doubt there was chloride of lead there, but he thought the rapidity with which the action took place quite negatived the idea that it was due to any impurity in the soil, and also the fact that when he tested there was a steady difference of potential of six volts. The pipe had had to be changed at intervals of about six weeks for several months in succession, and during that time there had been an earth fault on the mains of the Company which they did not know of. While that earth fault was on there were continual failures of the gas pipe. The damage was confined to one section of the pipe, and the electrolytic action occurred only at the point where there was an accidental contact with the earth. That was certainly preventable, and the imperfect means of localising and testing was the cause of that fault remaining so long. He had no doubt any such fault would not be left for any length of time now, since attention had been drawn to the matter. In the case of a tramway working with uninsulated returns precaution should be taken that the leakage did not hurt other people. They could not prevent its hurting something, but by the means he had suggested it might be confined to their own rails.

By Mr. FORWOOD: Having regard to his experience, he should say that the Leeds system might with proper precautions and proper watchfulness and testing (which was a most important point) be carried on without any damage to gas and water mains. Two volts was about the amount of electromotive force that was necessary to produce electrolytic action. The main object of the clause in the Electric Lighting Orders forbidding earth connections with houses was the protection of the consumers into whose houses electricity was brought. The Board of Trade had always been advised that an earth current should not under ordinary conditions, and with the conductors which were generally used, be taken inside houses, but with the approval of the Board of Trade and with the sanction of the Postmaster-General, to whom it might be an annoyance, they were permitted, under certain safe conditions, to use an earth connection for other purposes.

By the CHAIRMAN: Since he had been informed of Mr. Preece's experiments on the City and South London Railway with regard to leakage, which was a matter which had not been brought to his notice till the week before last, he had suggested to the engineer of the Company that he should carry out certain tests with the view of gaining information as to where his leakage occurred, what it amounted to, and how it might be prevented. The only time which was available for testing under the working conditions of that line was on Sunday morning, when the engineer took those tests in as nearly as possible the way in which he had asked him to do, with a steady current through the system of 140 amperes, which, as regards fall of potential, would be equal to a 280 current equally distributed. The result was to show a maximum difference of potential between their system and the gas and water pipes (which was one thing he was very anxious about) of 2½ volts, except at one station where there was a difference of potential of about 4 volts between the gas pipes and the negative terminal of their system. Considering those tests when they were brought to him on the Monday, he suggested that probably they would find a metallic connection at that point between their rails and the gas pipes, and the next day he was informed that that connection had been found, and he thought that was in a great measure the cause of the ringing of the bell which Mr. Preece had mentioned. He entirely agreed with Lord Kelvin in certain answers which he gave as to improvements which might be made in railways and tramways for preventing the injurious action such as he had described, the gist of which was that in his opinion certainly great improvements could be made by which, probably even under existing systems of working, interference could be avoided. It was impossible to absolutely avoid any interference between any two electric circuits on this earth, but practical interference was a very different thing. They had first of all to utilise the whole conductivity of their return rails; the more they increased the conductivity of the rails the more they diminished the loss of potential in the rails and the leakage of current outside. In the City and South London the sleepers were not creosoted, and conducted electricity more than they need. In the case of tramways, also, what they had to aim at was to take advantage of the whole conductivity and increase it by additional conductors to the return circuit, and adopt, as far as practicable, the same system which was used in the case of electric supply to maintain a uniform pressure throughout a large district. In the case of electric supply by the Board of Trade regulations, they were only allowed a variation from the proper pressure of 3 per cent. in their mains. If the tramway companies were to maintain a potential within 3 per cent. it would not interfere with anybody, but, of course, the conditions were not identical. A constant unvarying current would not affect telephones in the least, however much was escaping to earth, but in the case of tramways it was always varying. Sparking of the contact, sparking of the brushes, vibration in the motor, and in the way in which the motor was wound, was sufficient to cause the sudden variation. No doubt improvements such as he had indicated would be carried out to do away with that annoyance, and would not cause any very great expense, but he attached the greatest importance to systematic testing.

* Abstracted in *The Electrician*, Vol. XXIX., p. 675.

By Mr. BRUNNER: Up to the present, as was very natural, the efforts of the electric tramway and railway authorities had been directed to those sides of the question which dealt with getting the most return for their money, but he did not think there would be any unwillingness on their part to make the tests which he had suggested now that they realised the importance of them, and they would no doubt put the results on record, so that the Board of Trade could have access to them. He thought they would do that without any compulsion, though it might be advisable that they should be bound to produce the record of the tests when called upon.

By Earl RUSSELL: At present the companies had been so much occupied in getting powers to run at all, and had not had time to pay attention to the niceties of adjusting the brushes, and so on. They had been endeavouring to get the system into practical working order, which was the natural thing to do, and as regards interference they were probably leaving that until some amount of compulsion was put upon them.

Earl RUSSELL: You think they will do it when they have time?

The WITNESS: If they have a sufficient motive. He could not say if the double insulation system for tramways was practicable, as he had not sufficiently studied the question, but it certainly was a more complicated system, especially in the case of feeders. If they had a 10-mile line of tramway they must not attempt to bring the return on one line of rails along the whole length, but insulated feeders might be adopted.

By Mr. MOLLOY: Electrolytic action was a thing that could be avoided with ordinary care, and in the future there was no fear of any large extension of that danger to gas and water pipes. He did not see the necessity for any regulations to secure that object, but assuming suitable regulations were drawn up there was no danger to be apprehended.

By Lord CLIFFORD: There was just sufficient leakage from the Leeds Tramways to set up electrolytic action, and no doubt some such action was going on, but it was in the direction of the current and was not in such a position as to damage gas or water pipes, but would rather damage the rails.

By Major DARWIN: The effect of inductive action from tramways upon telephones might be experienced for some hundreds of yards, but as regards leakage there were so many things to be considered that it would be difficult to say where the effect might be stopped or where it might be found. It depended on what pipes were in the ground, the nature of the ground, and also on the volts lost in the ground.

Sir FREDERICK BRAMWELL was then examined by Mr. POPE on behalf of the Gas and Water Companies. He said that he had given attention to the subject of electrolytic action. In the case of electric lighting it could only be produced by accident, but in the case of tramways, like the Leeds tramway, with uninsulated returns, it was a constant and real danger. Major Cardew's proposition to connect the negative pole of the dynamo to the water pipes, it seemed to him, did not take account of the fact that they must have continuous water pipes. The pipes might stop, and they would have the gas pipes left unprotected. The water pipes, too, had joints which were absolutely impermeable by electricity. It must also be borne in mind that most water pipes were coated with Angus Smith's composition, a black varnish, which was not a good conductor of electricity. This was not a new subject to him, for it came before him in the case of Lane Fox against the Kensington Electric Lighting Company. In that case, the suggestion was made of using the water pipes as a return (they being included in the term "earth"), and the question of electrolytic action was raised, the conclusion at which he arrived being that it was dangerous and ought not to be allowed. He would like much more experience of Major Cardew's plan as to its effect on gas and water pipes before he could assent to the proposition that it would remove all cause of anxiety. In his judgment the only method of securing safety against electrolytic action was the proper insulation of both the outgoing and incoming conductor from the earth so that there should be no leakage whatever, except in time of accident, and in that case it would be very different from the harm done by interference with the telephones. The waste of a pipe by electrolytic action was due to the amount of the current and the time during which it acted. Supposing there were a failure from some accident; if perfect insulation and electrolytic action were set up it might go on, perhaps, for one day in the year, or for a week in the year, and the harm done would be in proportion to the time it went on. In the case of telephones the annoyance was immediate. In the case of the gas company it was dependent on the time and quantity, therefore any system which prevented heat and which had any imperfection would still be defective. He did not regard a provision for the prevention of such action as being prohibitory to electric traction. He could not imagine that legislation would ever allow the streets of London and the suburbs to be worked by means of overhead lines. If they did not, there was no other method except working by accumulators, which was perfectly feasible and innocuous, or by conveying the electricity in tubes underground. If the latter plan were adopted there was no difficulty in having both the incoming and outgoing mains in the tubes.

By Mr. WORSLEY TAYLOR: When he spoke of the Leeds system as being a real danger, in fact he had found none, but one of the things to be considered was that the harm was covered up. It might go on and nobody know anything about it until the rupture took place.

By Lord KELVIN: In the case of electrolytic action upon water pipes there was not much risk to life, but in the case of gas pipes being ruptured when the road was covered over with concrete, they knew nothing about it until the gas came into the area of the house and into the kitchen, the kitchen fire got hold of it, and the result was a serious explosion.

Dr. J. HOPKINSON was recalled, and stated that he had long held that there was a probability of oxidisation to the pipes from the currents meeting and passing through them, but it was only comparatively recently that he had realised how serious the disturbance might be. His view was that the only thing which could be done to protect against the oxidisation was to insulate the whole system of electrical conductors as used for tramways. To show that the danger to gas pipes was of a serious character, he produced a gas meter in which two holes had been eaten by the action of electricity. Paint would act slightly as a non-conductor, but it was easily scratched off. There had been many cases of very serious explosions occurring in the streets from undetected leaks from gas pipes. The worst thing that could happen would be that there should be actual metallic connection between the rail and the gas pipes. They might have the current leaving the gas pipe at one point and returning to it at another, and so causing oxidisation. Gas pipes were more or less moist. Gas companies, of course, did not trouble themselves much as to whether the soil in which they laid their pipes was moist or dry. Between the two flanges of the joint of a water pipe was a piece of millboard, which if dry was an insulator, but if wet it acted electrolytically. With an ordinary spigot joint he believed this would not occur. He thought culverts with slots in them were not found to interfere with traffic in any way.

By Mr. BALFOUR BROWNE: The gas meter which he had produced was a case of an accident occurring in an insulated system, but it had been allowed to exist for many months, when it should have been seen to at once.

By Earl RUSSELL: He did not agree with Sir Frederick Bramwell that the black varnish on the outside of the pipes would prevent them from conducting to the soil; the varnish was spread over a large area, and was very thin. He was not aware of cases occurring where flange pipes had been injured.

Prof. DEWAR was the next witness. He stated that his attention had been directed, purely from the chemical side, for some years past to the question of electrolytic action upon gas and water pipes. He was well aware of Papers dealing with the damage which had occurred in America, and especially called attention to the Paper on "The Electrolysis of Water Pipes," which appeared in *The Electrician* a fortnight ago.*

Mr. POPE: So that it is a danger present to the mind of those interested in electrical service, not only here, but on the other side of the water also?—That is quite clear.

What do you say is the condition which can alone remove the danger?—The only condition is the one foreshadowed by Sir Frederick Bramwell and Dr. Hopkinson; that is, of course, the removal of the possibility of electrolytic action, on the one hand, that something might be done by connecting with the negative pole the water mains. I ought to say that the suggestion appears also in this paper, and it was dismissed in America as impracticable unless it was connected with the gas mains as well: so they take a different view. I take the view that the proper course would be undoubtedly to have much more insulation.

Would you, therefore, rely, as a practical measure, on this connection of the negative pole with the water mains?—No, I would not. My serious difficulty is, of course, the chemical question of the corrosion of iron pipes in the sub-soil. In our time, many chemists have devoted their attention to that both at home and abroad; but the problem is an exceedingly complex one. It varies very much with the character of the iron, and very small pieces in chemical composition affect enormously the rapidity of the attack. Then in the sub-soils, where there is a large amount of drainage, the sub-soil is stored with carbonic acid and ammonia, along with nitrates, and these are conditions under which the pipes are oxidised. The principle of keeping a large metallic system practically connected with the negative pole would mean to transform the metal into a condition that would not be attackable, owing to an infinitesimal layer of hydrogen: but, unfortunately, the condition of the chemical fluid surrounding the pipes in the soil is exceedingly favourable to the removal of this minute layer of hydrogen.

So that the corrosive action takes place, although a remedy may temporarily be made available?—That is what I say; there is no guarantee that it will be uniform over that large metallic area of the pipes. I know of no real remedy but absolute insulation.

Mr. BALFOUR BROWNE: With regard to the Paper in *The Electrician*, having reference to electrolysis in America, how many tramways are run by electricity in the United States?—That I could not say. This was a special case dealing with Cambridge (Massachusetts).

Have you ever heard of any but that one case?—I have seen no other records as yet.

By Mr. BRUNNER: It was exceedingly difficult to localise leakage in a large system. Variations in the insulation could, no doubt, be recorded, but where to find the defect was another matter. His difficulty as a chemist was that, while you might save the equivalent electrolytic attack on the iron for so many points, that did not prevent the natural and corrosive attack being greatly accelerated by the indirect effect of the passage of the current. It was not only the equivalent to the current doing damage to the pipe by oxidation, but the question was, What would be the effect of this upon the ordinary rapidity of corrosion which took place in the sub-soil? He thought that in the majority of cases it would be accelerated. Many things had been done to protect water pipes, and nothing had been so successful as Dr. Angus Smith's coating of tar or pitch; but even this, not having the same coefficient of expansion as iron, cracked and came off.

Mr. FOULGER (Chief Engineer of the Gas Light and Coke Company) was the next witness. He stated that he had great difficulty in coping with escapes under the London streets that were concreted. The escape of gas percolated through the earth from the place of leakage a considerable distance. There was another danger which had recently been illustrated in Oxford-street; the concrete on which the pavement was laid formed almost a perfect arch, and the loose friable earth with which London roads were constructed was continually sinking, the consequence being that large cavities were left between the concrete and the earth. He

Digitized by Google

viewed the danger to the gas pipes with serious apprehension. The total loss of gas in transit amounted to 4 per cent., but less than 1 per cent. was due to leakage, the greater part being due to difference in the temperature at which the gas was registered at the works and the private houses. Cast-iron pipes put in a suitable soil were, he thought, practically indestructible; he had seen pipes that had been in the ground for upwards of 50 years which were as sound as a bell.

Mr. EPSTEIN (Managing Director of the firm of Epstein and Co.) was then examined and gave particulars of the Birmingham Central Tramways and calculations as to the cost of traction by accumulators.

Mr. W. H. CHRISTIE (Astronomer Royal) then gave evidence as to some disturbances in the instruments at Greenwich, owing to the working of the City and South London Railway. It had struck him as curious that the disturbances in the two circuits should have been the same approximately, and the only explanation he could suggest for their difference was that one of the earth-plates being near the river, the electricity was carried down by water, which was a better conductor. They had noticed another disturbance confined to the night hours, the only explanation they could make for which was that it might be due to the effect of some electric lighting near the river.

The CHAIRMAN: Are these observations of so great importance that we should put costly restrictions upon the Railway Company in order to protect you against them?—I think it is hardly of sufficient importance, from the scientific point of view.

This concluded the evidence, which will be laid before the Committee, and the Committee then adjourned.

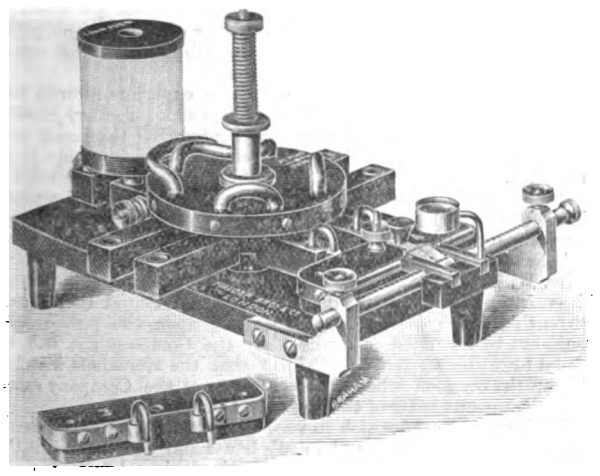
On Tuesday the speeches of counsel were taken, Mr. Pember, Q.C., addressing the Committee on behalf of the Telephone Companies; Mr. Moulton, Q.C., for the Railway Companies; Mr. Balfour Browne, Q.C., for the Municipal Corporations; Mr. Cripps, Q.C., for the traction interests; and Mr. Pope, Q.C., for the Gas and Water Companies. In regard to the application of Mr. Wallace, to be heard on behalf of the Electric Lighting Companies, the Committee decided that if, after discussion, they considered it advisable, they would give Mr. Wallace an opportunity of being heard.

City and South London Railway Bill.

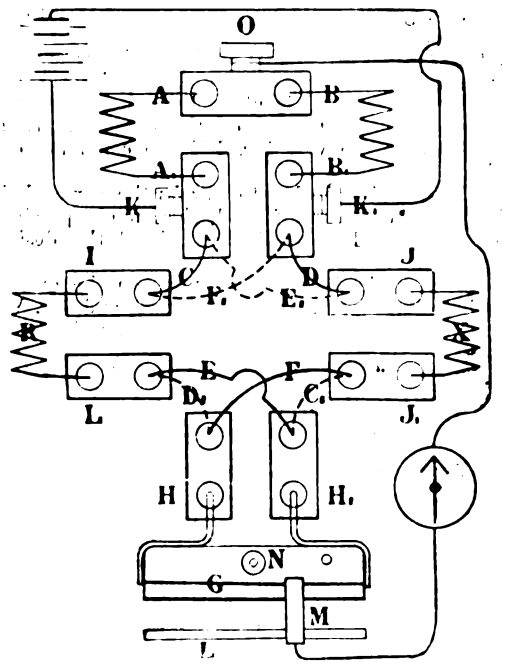
The Bill of the City and South London Railway Company to extend the time for the completion of the Subway, or Underground Railway, authorised by the Companies Act, 1890, came on Wednesday before Lord Wantage's Committee of the House of Lords; and the opposition of the Metropolitan District Railway Company and the London County Council being withdrawn, the Bill was referred to Lord Morley's Committee on Unopposed Bills.

PHYSICAL SOCIETY.

At a meeting of this Society on June 23, 1893 (Prof. A. W. Rücker, M.A., F.R.S., President, in the chair), Mr. F. H. NALDER exhibited a bridge and commutator for comparing resistances, by Prof. Carey Foster's method, the chief features of which are simplicity, compactness, long range, and great accuracy.



The instrument has been designed for commutating the resistances to be compared with respect to the ratio resistance coils and a series of bridge wires. It consists of copper bars mounted on an ebonite base, and furnished with mercury cups for making the necessary contacts. At A A_1 and B B_1 are the cups for the ratio coils which are wound upon one bobbin and usually of the value 1ω, 10ω, 100ω, and 1,000ω on each side. At I I_1 and J J_1 are placed the resistances whose difference is to be measured, and at G is the bridge wire mounted on a detachable frame, with the key M which runs on the divided rod L for making contact. C D E F show the commutator connections in the first position, and after commutation in the position C_1, D_1, E_1, F_1, as indicated by the dotted lines. In order to commutate the coils R and X, the ebonite plate upon which the connections C D E F are mounted is drawn up against the spring which presses the contacts into their respective cups, until the guide pin is lifted out of its recess, the plate can then be turned through 180deg. till the contacts are in the position shown by the dotted lines marked C_1, D_1, E_1, F_1; the galvanometer is then brought to zero by moving the contact key M into another position on its wire. The battery connections are shown at K K, and those of the galvanometer at M O.



In order to obtain a wide range of measurement instead of using a long wire, a number of short bridge wires are provided, usually about 10, though, if necessary, this number need not be considered the limit. The plate upon which each wire is mounted is detachable, as already stated, and in addition to the milled head H two steady pins are fixed in the base of the commutator, so that it or any of the series can always be replaced accurately in position with respect to the scale and key. A considerable variation of resistance of the short bridge wires shown will not vitiate the accuracy of the measurement.

Mr. W. R. PIDGEON and Mr. J. WIMSHURST each read a Paper on

"An Influence Machine,"

and exhibited their machines in action. In designing his machine, Mr. Pidgeon has endeavoured (1st) to make the capacity of each sector large when being charged, and small when being discharged; (2nd) to prevent leakage from sector to sector as they enter or leave the different fields of induction; and (3rd) to increase the capacity of the machine by making the sectors large and numerous. The first object is attained by arranging fixed inductors of opposite sign to the sectors near the charging points, and of the same sign near the places of discharges. Objects 2 and 3 are secured by embedding the sectors in wax, run in channels in the ebonite discs which form the plates of the machine, and carrying wires from each sector through the ebonite, each wire terminating in a knob. In this way the sectors can be placed much nearer together than otherwise without sparking back. By setting the sectors skew with the radius, they are caused to enter the electric fields more gradually, consequently the potential difference between adjacent sectors is kept comparatively small. Experiment showed that the use of the stationary inductors at the charging points increased the output threefold, and as compared with an ordinary Wimshurst, the output for a given area of plate passing the conductors was as 5·6 : 1. The recovery of a machine after a spark had occurred was particularly rapid.

Mr. Wimshurst's new machine consists of two glass discs, 3ft. 5in. diameter, mounted about ¾in. apart on the same spindle. Both plates turn in the same direction. Between the discs are fixed four vertical glass slips over 4ft. long, two on each side, and each covering about three-eighths of a disc. Each slip carries a tinfoil inductor, which has a brush, touching lightly on the inside of the adjacent disc, on its leading edge. Collecting and neutralising brushes touch the outsides of the discs, and the few metallic sectors attached thereto. An account of some experiments made to determine the efficiency of the machine was given. The author also showed that when all the circuits of the machine were broken, it still continued to excite itself freely, and sparked from the discs to the hands when brought near.

Digitized by Google

In a written communication, Prof. O. LODGE said his assistant, Mr. E. E. Robinson, constructed a machine on lines similar to Mr. Pidgeon's a few months ago, and had now a large one nearly completed. Mr. Robinson's fixed inductors are carried on a third plate, fixed between the two movable ones. The sectors are quite small, and neither they nor the inductors are imbedded. On close circuit, the machine gives a large current, $\frac{1}{10000}$th of an ampere, and on open circuit exceedingly high potentials. In Dr. Lodge's opinion, Mr. Pidgeon attaches too much importance to his sectors and their shape.

Mr. J. GRAY wrote to say that stationary inductors, enclosed in insulating material, would probably give trouble at high voltages, because of the surface of the insulator becoming charged with electricity of opposite signs to that on the inductor. He suggested that this might explain why Mr. Pidgeon could not obtain very long sparks.

Prof. E. V. BOYS inquired as to how far the wax made insulating union with the ebonite, for if good, glass might possibly be used instead of ebonite. He greatly appreciated the design of Mr. Pidgeon's machine.

After some remarks by the PRESIDENT on the great advances which had been made, Mr. PIDGEON replied, and Mr. WIMSHURST tried some further experiments with a small experimental machine.

A Paper on

"A New Volumeometer,"

by Mr. J. E. MYERS, B.Sc., describing the developed form of Prof. Stroud's instrument, was, in the absence of the author, taken as read.

Mr. R. W. PAUL exhibited a compact form of sulphuric acid voltameter of small resistance. The voltameter is a modification of a pattern designed at the Central Institution, in which the rate of decomposition is determined from the time required to fill a bulb made in the stem of a thistle funnel. He also showed a handy form of Daniell cell devised by Prof. Barrett. When not in use

the porous pot containing the zinc is removed from the copper sulphate solution, and placed in a vessel containing zinc sulphate, or sulphuric acid.

A Paper on

"Long-Distance Telephony,"

by Prof. J. PERRY, F.R.S., assisted by H. A. BEESTON, was read by Prof. PERRY. The case of a line of infinite length, having resistance capacity, self-induction, and leakage, is taken up, and the state of a signal as it gets further and further away from the origin, is considered. Taking the shrillest and gravest notes of the human voice to have frequencies of about 950 and 95 respectively, the distance from the origin at which the ratio of the amplitudes of these high and low-frequency currents is lessened by $1/m$th of itself, has been determined when $m=4$ for different values of leakage and self-induction; and under similar conditions the distances at which the relative phase of the two currents become altered by $1/n$th of the periodic time of the most rapid one, have been worked out for $n=6$. The results are given in the form of tables, from which it appears that if there was no self-induction, increasing the leakage increases the distance to which we can telephone, whilst if there were no leakage increasing the self-induction increases the distance. When self-induction and leakage are not too great, increasing either increases the distance, and for particular values the distances become very large. At the end of the Paper, tables of general application are given, from which the limiting distances for any time can be readily found by multiplying the numbers by simple function of the contents of the line.

Mr. BLAKESLEY said that some ten years ago he discussed the subject where capacity and resistance were alone considered, and now pointed out that when self-induction and leakage were introduced the equations were still of the same form. He also suggested how terminal conditions on lines of finite lengths might be easily taken into consideration.

Prof. PERRY, in reply, said the introduction of self-induction and leakage rendered the calculations much more laborious, and that the terminal conditions were much more complicated than Mr. Blakesley supposed.

LEGAL INTELLIGENCE.

Cook v. St. James' and Pall-mall Electric Light Company (Limited.)

This action came before Mr. Justic North in the Chancery Division on Tuesday. It was brought by the trustees of the Windham Club (in St. James's-square), on behalf of the club, complaining of a nuisance caused by noise and vibration proceeding from the works of the defendant Company, which are situated in Mason's-yard, about 45ft. from the club. The plaintiffs claimed an injunction to put a stop to the alleged nuisance.

Sir H. Davey, Q.C., and Mr. T. L. Wilkinson were for the plaintiffs; Mr. Cozens-Hardy, Q.C., Mr. Moulton, Q.C., and Lord Robert Cecil were for the defendants.

Sir H. DAVEY opened the plaintiff's case, and read some correspondence, but, before any witnesses were called, an arrangement was come to between the parties, by which, by consent, and without prejudice to any question, the defendants undertake that if in the opinion of an engineer, to be named by the Board of Trade or agreed upon between the parties, the working of the machinery in Mason's-yard does now or at any time hereafter shall cause any annoyance by vibration or noise to the Windham Club, they will forthwith make all such reasonable alterations or additions as the engineer shall direct for the purpose of remedying the same. No order was made by the Court, except that the defendants pay the costs of the action. Liberty to apply.

Dart v. Electricity Supply Corporation.

This action, which engaged the attention of Mr. Justice Cave and a special jury on Monday, Tuesday, and Wednesday, was a claim for damages to premises and for injury to health on the part of the plaintiff, Mr. Wm. Dart, of Southampton-street, Strand, caused by the working of the machinery at the central station of the defendant Company, in Maiden-lane.

Mr. Willis, Q.C., and Mr. Ellis appeared for the plaintiff, and Mr. Fletcher Moulton, Q.C., and Mr. Turrell for the defendants.

Mr. WILLIS stated, in his opening speech, that in the year 1888 Messrs. Gatti started an electric installation in Maiden-lane, but no annoyance was caused by it. In 1891 the works were taken over by the defendant Company, and fresh machinery was put in. Vibration was set up in the plaintiff's premises to such an extent that his assistants and his tenants complained greatly, and his own health was shattered, and he was unable to attend to his business properly. Some of his tenants had left after complaining of the vibration, and he had been unable to let his rooms since.

Mr. DART said he first noticed the disturbance in the Autumn of 1891; it continued until April in the following year, was much modified in the summer months, and was intensified throughout the winter. It was impossible for anyone to sit in the rooms without noticing the vibrations, and being disagreeably affected by them. His assistant had frequently been unable to sleep at night, and his own health had suffered. One of the firms of Messrs. Gatti had visited the house, but did not admit that there was any great amount of vibration, but a Mr. Clarke, representing the defendant Company, at a subsequent time said there was certainly some vibration in the upper part of the house. He had never experienced any discomfort from the traffic in the street, nor from the other machinery in the neighbourhood.

Mr. EDWARD SEGUNDO gave evidence of experiments with mercury to test the extent and character of the vibrations, which coincided with those he observed at the defendant's works.

Mr. P. P. KIPPING gave the results of experiments with microphone and telephone receivers, showing vibrations of a pulsatory character.

Mr. TERRELL, for the defence, contended that the house was old and dilapidated, and easily shaken by persons walking about in it, by the traffic in the streets and by the printing machinery in the neighbourhood.

Dr. JOHN HOPKINSON, F.R.S., gave particulars of several visits to the plantiff's shop, and of failing to detect any vibration attributable to the Company's works; he did, however, find that the windows rattled, and the walls shook when there was a passage of traffic in the street.

Mr. W. H. PATCHELL (Electrical Engineer to the Company) produced his registers of the output at the works, and stated that the amount of current produced was entirely dependent upon the public demand, and could not be regulated or modified by the Company; it had been suggested by witnesses for the plaintiff that the vibrations were less noticeable on the occasion when representatives of the Company examined the premises because some of the power had been shut off.

The jury expressed a wish to view the premises, and arrangements were made for them to visit the plaintiff's house and the defendant Company's works on Wednesday evening. His lordship, therefore, deferred his summing up until Thursday morning.

The jury after their visit returned a verdict for the defendants. His Lordship certified for a special jury, but demurred to an application for a stay of execution. This, however, was withdrawn upon the assurance of defendants' counsel that every facility would be afforded plaintiff whilst considering the question of carrying the proceedings further.

A Long Telephone Line.—It is reported to be the intention of the Automatic Telephone Company of Canada to establish telephonic communication between Halifax and Vancouver, by means of an overhead line crossing America from east to west. The distance is about 3,800 miles.

CORRESPONDENCE.

TESTS OF STEAM DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With special reference to some excellent results recently obtained from a large Willans-Holmes combination steam dynamo, we beg to enclose a sheet of tests of a Willans-Crompton combination steam dynamo tested this week, which although only half the size of Messrs. Holmes's combination, shows results practically as good. We only ask you to publish these figures as an additional proof that the manufacture of continuous-current dynamos is, at all events in England, now so well understood that combined efficiencies exceeding 86 per cent., corresponding to commercial efficiencies of 95 per cent. in the dynamo are the rule and not the exception.—Yours, &c,

CROMPTON & CO., LIMITED.

MUTUAL ATTRACTION OF VACUUM TUBES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your editorial note at the conclusion of my letter in your last issue, I beg to say—(1) The attractive force between the tubes ceases at once on breaking the current; (2) the calculation can easily be made as to the magnitude of the force. By the roughest of tests ½oz. was about the value. During the autumn I hope to publish some more accurate details, together with some other phenomena which are interesting.—Yours, &c., DAVID SALOMONS.

June 24, 1893.

THE PRICE OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit me to reply to your strictures on my letter of 13th inst. You write as if I had advocated the immediate introduction of an accumulator into every separate consumer's premises; but this was not my meaning. I do not propose that the whole general supply shall be through accumulators, and I said the day load was to be "looked for," not to be *at once* had, "in a large extension of the use of accumulators close to the lamps;" though I certainly think the time for this extension is very near. I added that "where circumstances suited, of course, the battery might be arranged to supply a group of houses." My idea is to get the battery on consumers' premises, so as to have it as near as possible to the lamps (and thus reduce the cost of mains to a minimum), and save the rent of premises for sub-stations.

To meet your point as to the amount of capital required, I proposed that consumers should pay 5 per cent. interest thereon. It seems to me that the whole question of the extended use of accumulators is a matter for special consideration in each case, depending very largely upon the price at which current can be supplied at times when the direct demand is small.

Now, as to cost of maintenance: the coming average should be at least equal to the past best, and as the E.P.S. Company now undertake contracts for maintenance at from 5 to 15 per cent., averaging "under 10 per cent.," my estimate of 7½ per cent. in the near future does not seem to me out of the way. To test the matter I have written to the Epstein Company asking for information as to first cost and maintenance that I might make use of, and they reply:—"For the supply of a large number of batteries your estimate of the cost, viz., £2 per lamp is rather over than under the mark, and even if many small-capacity batteries be distributed throughout the electrically lighted area as mentioned in the editorial, we would have no hesitation whatever to undertake their maintenance for an unlimited period at the rate of 7½ per cent. per annum on their net invoice value."

The cost of a small E.P.S. battery, allowing what seems a not unlikely discount for a large order, works out as follows:—

	£	s.	d.
55 K13 cells, glass	143	0	0
Trays and insulators	5	14	7
Glass sheets	0	13	9
Stands	8	11	0
Erection	4	5	0
List price	162	4	4
Deduct for trade, cash and contract discounts 20 per cent.	32	8	10
Net cost of battery	129	15	6

This battery would be capable of running 64 60-watt lamps for nearly five hours. Larger batteries would make a somewhat better showing.

But here another consideration comes in; after next November it is practically certain that, with lamps at a fourth or fifth of their present prices, they will be run at a higher efficiency, and an allowance of 3 watts per candle-power will be a safe one. (The Zürich Incandescent Lamp Company are now advertising central-station lamps at 2·6 to 2·7 watts per candle-power.) This will reduce the cost of accumulators for any given amount of light by 20 per cent., as compared with the foregoing.—Yours, &c., W. S. BOULT.

60, Castle-street, Liverpool, June 20, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Urban Sanitary Authority for the district of Ealing invite tenders for—(1) Engine and boiler-house, buildings, &c., and accessories; (2) the provision and laying of mains, transformers, and accessories; (3) the wiring of public buildings, provision of fittings and accessories. Further information will be found in our advertisement columns, and plans, specifications, and all other complete particulars, can be obtained of Messrs. Bramwell and Harris, engineers, 5, Great George-street, Westminster, S.W.; or of Mr. Charles Jones, C.E., Surveyor to the Local Board, Ealing. Tenders for each contract must be sent in, addressed to the Chairman of the Ealing Local Board, before 12 o'clock, on Tuesday, July 18th next.

——— Tenders are required for the lighting by gas or electricity of the city of Belem, Gram Pará, Brazil. Particulars can be obtained at the Brazilian Consulate, 6, Great Winchester-street, London, E.C.

TENDERS ACCEPTED.—The Cardiff Lighting Committee on Monday had under consideration the tenders received for the supply of machinery and apparatus for an electric lighting central station. Out of 26 tenders received eight were from firms offering to supply everything required; but Mr. Massey, the electrical engineer, said that by dividing the contracts a sum of about £200 would be saved, and the following tenders were therefore accepted:—Messrs. Davey, Paxman, and Co. (Colchester), boilers; Messrs. James Watt and Co. (Birmingham), condenser; Messrs. Siemens Brothers and Co., Limited (London), dynamos, switchboard, transformers, &c.; Messrs. Johnson and Phillips (London), lamps and cut-outs. The total amount of the accepted tenders is £10,242, but the consideration of the tenders for lamp posts having been deferred, about

Digitized by Google

another £200 will eventually be added to this total. The tenders for the whole of the machinery and apparatus were as follows :—

John Fowler and Co., Leeds (Limited), without boilers...	£11,600
S. Z. de Ferranti (Limited)	12,700
Brush Electrical Engineering Company (Limited)	12,200
Latimer Clark, Muirhead, and Co. (Limited)	11,500
Crompton and Co. (Limited)	11,200
Johnson and Phillips	11,000
Siemens Bros. and Co. (Limited)	10,900
Woodhouse and Rawson United (Limited)	10,800

TENDER ACCEPTED.—The Holborn District Board of Works have accepted the tender of Messrs. Verity and Sons for the electric lighting of the Town Hall, the amount being £400.

BANKRUPTCY.—The public examination of Mr. William M'Whirter, lately carrying on business at Govan as an electrical engineer, was held on Friday, when the trustee stated that he had received full explanation regarding the estate, and he had no further questions to ask. The bankrupt's examination was closed.

DEED OF ASSIGNMENT.—Messrs. Austin and Myers, trading at Florence Works, Amberley-road, Armley (Leeds) as manufacturing electricians and electrical engineers, have made an assignment of their property for the benefit of their creditors. The liabilities are given as secured and partly secured, £275 ; unsecured, £270. 7s. 2d. ; whilst the assets are returned at £90. Mr. Thomas Grisdale, 37, New-street, Huddersfield, is the trustee. The creditors over £20 are as follows :—

Joseph Longley, Bradford	£275
Joseph Gration, Leeds	24
Samuel Greaves, Leeds...	70
Alabaster, Gatehouse, and Co. (*Electrical Review*), London...	47
Industries (Limited), London	38
Walter F. Glover and Co., Manchester	21

FOWLER, LANCASTER, AND CO. (LIMITED).—The petition for a winding-up order against this Company was last week, by consent, dismissed without costs. The Petitioners, the Electrical Company (Limited), desired an arrangement to protect the unsecured creditors in the voluntary liquidation, and a gentleman had been appointed with whom they were satisfied.

BIRMINGHAM TELEGRAPH FACTORY (LIMITED).—Judge Chalmers resumed the adjourned examination into the affairs of this Company, at the Birmingham County Court, on Thursday last week. The hearing had been postponed in order that affidavits might be prepared, and an opportunity given for the cross-examination of certain Directors of the "Factory." These affidavits were now read, and Mr. Fowler was cross-examined as to £3,000 worth of shares in the "Factory," held by certain of the Directors of Fowler, Lancaster, and Co. The "Factory" was indebted to Fowler, Lancaster, and Co. at the time the shares were allotted, the Directors being trustees on behalf of the latter Company. It was argued, on the one side, that these shares were given as a set-off, and were therefore paid for ; and on the other hand that the trustees were liable to pay for the shares and thus become contributaries to the estate of the Company. At the end of the arguments his Honour reserved judgment.

THOMSON-HOUSTON INTERNATIONAL ELECTRIC COMPANY.—Our advertisement columns contain a notice that Mr. W. S. Graff-Baker, who has represented the traction interests of the above Company in England for some years past, has severed his connection with the Company, in order that he may devote the whole of his time to the business of the Electric and General Contract Corporation, of which he is Managing Director. Future communications intended for the Thomson-Houston International Electric Company should be addressed to the European offices, 27, Rue de Londres, Paris ; or to 38, Parliament-street, London, S.W., where the Company continues to carry on business.

LEA, SONS, AND CO.—This firm send us an advance copy of their new electric light fittings catalogue and price list. The catalogue is in single sheets, so that the prices of fittings required for any special purpose can be readily obtained. Many of the designs are in the very best taste, and as proof of the care with which the sheets of illustrations have been prepared, Messrs. Lea, Sons, and Co. inform us that the sheets of designs are hand-painted. The list is in every way a very handsome production.

MESSRS. GILBERT AND CO.—This firm have secured the contract for the electric lighting of the large Philharmonic Restaurant at Cardiff.

MESSRS. SHIPPEY BROS.—This firm inform us that they have been made agents for the National Electric Manufacturing Company. Their new catalogue includes alternators, transformers, and electric lighting fittings, and the usual large variety of apparatus which goes to make up an American "system." The alternators appear to be not unlike the Westinghouse, with smooth cores and cast-iron fields.

DISTRICT MESSENGER AND ELECTRIC CALL COMPANY (LIMITED). Some particulars are published of the amount of business being done by this Company, and it appears that nearly 12,000 houses in London are connected by the electrical call apparatus belonging to the Company. An interesting account of the Company's business is given in a recent issue of *Cassell's Saturday Journal*.

ELECTRICAL CRANES.—We have received from the Ateliers de Construction, Oerlikon, Zürich, their latest catalogue of electrical cranes and hoists. A number of illustrations accompany the list, which is in German.

MESSRS. RUSSELL AND CO.—The *employés* of this firm had their annual holiday on the 17th inst. The entertainment provided consisted of a trip on the river in a steam launch, with dinner at Staines, and tea at Kingston.

ABERDEEN.—A meeting of the shareholders of the Northern Co-operative Company (Limited) was held on Tuesday last to consider the question of the electric lighting of their central premises. The Buildings Committee had reported that Prof. Kennedy estimated the cost of the machinery and apparatus necessary for supplying 500 8 c.p. lamps, exclusive of wiring, at £625, and that the annual cost would be about £260. The Committee did not think there would be much difference between the cost of the electric light and gas ; but, taking into account the greater amount of light from the electric current, and the absence of heat, and deterioration caused to goods by the fumes of gas, they unanimously recommended the Company to adopt the electric light. Some discussion ensued, and in the end the consideration of the matter was adjourned.

ADELAIDE (SOUTH AUSTRALIA).—At a recent meeting of the Municipal Corporation the report of the Committee appointed at the Postal and Telegraph Conference held at Hobart in 1892, for the purpose of drafting a code of rules and regulations for erection of electric light and power wires was read and considered, and the Committee recommended that in any scheme adopted by the Council for lighting the city street lamps by electricity the Council should insist on the regulations drafted by the above Committee being strictly adhered to. A scheme is on foot to introduce the electric light into the public streets.

A MILITARY TELEGRAPH CAMP.—The *Daily Graphic* of Wednesday contained an illustrated description of the work done by the Telegraph Battalion of the Royal Engineers at their annual training and drill in the Duke of Norfolk's Park at Arundel.

BALLARAT (AUSTRALIA).—Mr. Lee Murray has presented a report to the City Council of Ballarat regarding the lighting of the district by electricity. He estimates the total cost of the generating plant at £25,105, and the interest on outlay and maintenance at £4,825 The matter is under the consideration of the City and Town Councils

BARNET.—On Tuesday last a Parliamentary Paper was published in reference to the Electric Lighting Provisional Order which the Barnet Local Board has applied for in order to keep out outsiders. Lord Playfair has given notice of an amendment to Clause 6, to be moved on the third reading of the Bill dealing with this and similar orders. "Provided always that if the undertakers or any such owner at any future time apply to Parliament to repeal or amend the foregoing provisions in accordance with the report of a joint committee of both Houses of Parliament (whether such report shall or shall not be retrospective in its recommendations), such owner or the undertakers, as the case may be, shall not be entitled to oppose such application except on details." The matter was discussed at the Local Board meeting, and was unanimously approved, Mr. Morse saying that it was of a valuable character.

BECKENHAM.—At the last meeting of the Local Board letters were read from the Board of Trade stating that they proposed to release to the Crystal Palace and District Electric Supply Company (Limited) the deposit made by them under their Order, and the Board proposed to issue a licence to the Company in respect of the extended area of supply conditionally acceded to by the Local Board. The clerk explained that the Company had obtained one Provisional Order to supply a part of the district of the Local Board, and they now desired to extend that district, for which a second Provisional Order would be necessary, but the Board of Trade had decided not to grant this second Order unless the Company consented to the insertion of a clause which would enable the Local Board to purchase the Company's undertaking in this extended district.

BEDFORD.—At their last meeting the Urban Sanitary Authority had under consideration the report of the Electric Light Sub-Committee, recommending the acceptance of the tender of the Bedford Electric Light Company to undertake and carry out the Provisional Order which has been obtained. After considerable discussion, it was decided to refer the report back to the Sub-Committee, in order that they might treat with the Company, and further report.

BRIGHTON.—At the last meeting of the Board of Guardians a discussion arose on the question of the rental paid by the parish to the National Telephone Company for the use of the telephone.

Digitized by Google

The Chairman said the Telephone Company had recently altered their regulations, and that call office subscribers had now to pay a penny or deposit 5s. for a key before they were allowed the use of the telephone. The clerk pointed out that these regulations only referred to call offices. Mr. Bennett said he believed the regulation was put in force with the view of ultimately abolishing the call offices altogether.

CARLISLE.—Messrs. Siemens Brothers are laying conductors for private lighting, and considerable progress is also being made with the cables for public lighting. The southern portion of the town is practically completed.

CITY OF LONDON.—The electric lighting of the Guildhall is to be extended to the museum, at an estimated cost of £360.

DUNDEE.—At the annual meeting of the Dundee Gas Commission, held last week, it was stated that the electric light had received a fair amount of support from the public, and was giving satisfaction. It was decided to reduce the price of gas by 5d. per thousand, and the price of the electric current was fixed at 5d. per unit. A communication asking the Dundee authorities to join several large English towns in a Parliamentary representation respecting the vexed question of tramways and telephones was mentioned, and it was agreed that as Dundee was not directly interested it was unnecessary for the Commission to take any action.

HADDINGTON.—The question of renewing the lease of the East Mill, the property of the Council, came before that body at their last meeting, and Mr. Falconer stated that, as there was a possibility of the town being lit by electricity the power of the water at the East Mill might be utilised for that purpose. It was agreed to postpone any decision for a time. An inquiry is meanwhile to be made as to the strength of the water power, and whether it would be sufficient for the purposes of the electric lighting scheme.

LANCASTER.—A Local Government Board inquiry was held on Wednesday at Lancaster by Major-General Crozier, R.E., in connection with the application of the Corporation for power to spend £25,000 on the electricity supply. Mr. W. Geipel, M.I.E.E., attended on behalf of the Brush Company, and explained the details of the scheme. The system adopted is the three-wire low-tension continuous current, with a set of storage-cells for the day load. Three direct-driven two-pole dynamos are being made at Falcon Works, the whole of the installation being in the hands of the Brush Company.

LAMBETH.—The Board of Guardians have decided to obtain an expert's opinion as to the practicability, cost, and ultimate economy of lighting the Renfrew-road Workhouse and Infirmary by electricity.

LLANGOLLEN.—Mr. C. L. Hett, hydraulic engineer, has submitted his report on the proposed scheme for utilising the water-power of the river Dee for the electric lighting of Llangollen. He reports that with an additional 5ft. fall at the Llangollen Mill there would be sufficient power to light the town, that no alternative steam power would be required, and that this would not, under ordinary circumstances, interfere with the working of the mill. Mr. Hett estimates the total cost of the water-power installation to be £3,000.

LONDONDERRY.—Satisfactory progress is being made with the building of the central station in Strand-road. The whole of the work, including the laying of the street mains and the erection of the lamp pillars, is to be finished during the month of September.

MAIDSTONE.—The Town Council had before them at their last meeting the report of the Electric Lighting Committee, which stated that they had advertised for information as to the terms on which a company or firm would undertake and carry out the powers granted under the Maidstone Electric Lighting Order, and that of the five replies received they were of opinion that the terms offered by Messrs. Sharp and Kent and Messrs. Bourne and Grant were the most favourable. Messrs. Sharp and Kent proposed to undertake the whole of the public lighting, the Local Authority guaranteeing a minimum sum per annum of £500. The Authority would have the right to purchase the undertaking at the end of ten years by paying for the plant and five times the previous year's net profit for the goodwill. The Authority would be required to find a suitable site for the works, for which Messrs. Sharp and Kent would pay an agreed rental. A discount of 25 per cent. from the maximum rate charged to be allowed for public lighting, a minimum annual payment to be guaranteed. Messrs. Bourne and Grant would agree either to an absolute transfer to them of the Order or would enter into a contract. In the former case the firm would submit a working scheme for the approval of the Authority, and the Authority would have the option of purchasing the undertaking at the end of 21 years; if a contract were entered into the Authority would undertake to purchase the undertaking in 21 years. After some discussion the whole matter was referred back to the Electric Lighting Committee for further consideration. It is still possible, however, that the Local Authorities will keep the Provisional Order in their own hands.

MANCHESTER.—The application of the National Telephone Company for leave to lay their wires underground came before the last meeting of the City Council, and after considerable discussion it was resolved, "That the Paving, Sewering, and Highways Committee be authorised to negotiate with any telephone company or private owners, or the Postal Department of the Government, on the subject of underground telephone wires; that before carrying any arrangements into effect the Committee be requested to present a special report to the Council, and that until such report has been considered and sanctioned by the Council no arrangement whatever be entered into by the Corporation."

MELBOURNE (VICTORIA).—At a recent meeting of the South Melbourne City Council the Mayor intimated that he, with the City Surveyor, had recently met in conference with the mayors and surveyors of the St. Kilda and Prahran councils, with the view of ascertaining the best means of lighting the streets of the three cities, the gas supply being of such an inferior character. Councillor Smith, M.L.A., expressed an opinion that the matter was a very ticklish one, and should not be touched at present. Lighting the streets by electricity had been tried in several places, and had not always proved a success. He thought that as the City Corporation of Melbourne was expending a large amount of money to try the experiment it would be well for the South Melbourne Council to await the issue. After a brief discussion it was resolved to submit the matter to the consideration of the Legislative Committee.

NEWCASTLE (N.S.W.).—The City Council, at a recent meeting, decided to take over the electric plant from the contractors for the sum of £9,250.

NORWICH.—It will be seen from the report in another column of the recent meeting of the Norwich Electricity Company (Limited) that the Directors have decided to charge half-price for electric current *after* eight o'clock in the evening. We understand that the Directors have, in consequence of an application from the trustees of a place of worship using the electric light, decided to allow the reduced rates to commence at 7 o'clock on Sundays. It is anticipated that this concession, which will make electric light compare very favourably in point of cost with gas, will bring about the general use of the former illuminant in places of worship in the district.

OSWESTRY.—The Town Council will on July 17th consider an adjourned application from the Oswestry Electric Light and Power Company (Limited) for the Council's sanction to an intended application to the Board of Trade for a licence.

ORPINGTON.—A scheme has been prepared by Mr. J. Torr Todman for the electric lighting of Orpington. He proposes to use the high-tension alternating current at 2,000 volts for the main current, to be reduced to 50 or 100 volts for the sub-circuits. The central station would be at a place known as Hodsell's Mill, where sufficient power could be obtained from existing steam engines to run 250 16 c.p. lamps, which, with additional boiler power, might be increased to 350 or 400. The estimated cost of the plant, laying mains and branch cables, and fixing transformers, is £905, and the annual working expenses are put down at £277, which it is calculated would be well covered by the receipts. The Orpington Committee of the Bromley Rural Sanitary Authority have recommended that all facilities should be given for the supply of the electric light to the district and that the necessary permission be given for breaking up the roads.

ST. LUKE'S (CHELSEA).—The Board of Trade have revoked the St. Luke's (Chelsea) Electric Lighting Order, 1891.

SEAHAM HARBOUR.—The members of the Seaham Harbour Co-operative Society have decided to light their very extensive premises by electricity.

SOUTH STONEHAM (HANTS.).—The tender of Mr. Thomas Glyde, of Sir George's-road, Freemantle, was accepted for making electric communication between the infirmary and the workhouse, at £4. 9s.

YORK.—The Electric Lighting Sub-Committee have had under consideration the several tenders for the lighting of the city by electricity. The majority of the tenders were from companies adopting the high-tension system, and the Sub-Committee recommended the adoption of one of these tenders. At a meeting of the full Committee, however, it was deemed advisable that a digest should be prepared of Prof. Kennedy's reports, so that they would be in possession of the main features of both the high and the low-tension systems. When this digest is prepared the full Committee will meet and finally decide.

ELECTRICAL TRACTION AND LIGHTING ON TRAMWAYS.

A special meeting of the Tramways Institute was held yesterday, at the Holborn Restaurant, under the presidency of Mr. W. J. Carruthers Wain, the President. The formal business of re-election of the President, Vice-Presidents, and Executive having been completed,

The SECRETARY (Mr. J. G. B. Elliot) read the report of the Council, which stated that at the Birmingham meeting the members had the opportunity of inspecting the new electric installation by means of overhead wires on a portion of the South Staffordshire line, from Wednesbury to Walsall and Bloxwich and to Darlaston; and at Liverpool the privilege of inspecting the Liverpool Overhead Electric Railway. The Council were gratified at the success which had attended their efforts to introduce to the notice of members all the newest developments of the application of modern science to traction. The matters discussed at these two meetings included, amongst others, electric traction by overhead wires and the claims of telephone companies and their opposition to electrically-worked tramways. The most important events of the year, from a traction point of view, had been the opening of the South Staffordshire Electric Tramways and the Liverpool Overhead Electric Railway.

The PRESIDENT, on moving the adoption of the report and accounts, said that as regarded electrical traction this country did not show the progress that had been made by other countries. Taking the United Kingdom they had had 33 miles of electric tramway built during the 10 years since the first electric line was opened in 1883, viz.: the Portrush and Giant's Causeway. In America the idea of electric traction was only taken up in 1887, but since that time their convenience had been so realised that there were at the present time no less than 436 miles of electrical lines, with 3,532 miles of track, and 5,581 cars carrying 250,000,000 passengers annually. This only showed what could be done in countries where there was freedom and not annoying restrictions (hear, hear). He moved the adoption of the report and accounts.

Mr. MASON seconded the motion, which was carried.

Mr. L. EPSTEIN then gave particulars in regard to "Recent Results of Accumulators (Electric Traction)." He stated that the use of the accumulators supplied by his firm to the Birmingham Central Tramway Company had proved very satisfactory, and he asked the corroboration of the President, who was the Chairman of that Company, as to the facts.

The PRESIDENT said that the assertion of Mr. Epstein was accurate, and under severe difficulties of gradients and snowy weather the result had been most satisfactory.

In reply to questions, Mr. EPSTEIN said that the accumulator system was cheaper than the overhead or conduit system of electric traction.

Mr. H. U. WOLLASTON then dealt with a Paper upon the lighting of omnibuses and tramcars, and the Bristol electric lamp for this purpose was also submitted to the meeting by Mr. Edwin Freund. The Papers stated that electricity could beat gas in the matter of price for this purpose.

After some discussion, a vote of thanks to the President closed the proceedings.

COMPANIES' MEETINGS AND REPORTS.

Electric and General Investment Company (Limited).

The fourth ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Tuesday, under the presidency of Mr. George Herring.

The SECRETARY (Mr. J. Cecil Bull) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I am sure, if all the shareholders were present they would fully agree with the Directors in regretting the loss of their former Chairman, the Duke of Marlborough, and, speaking for myself, I can only say that I felt the loss very much indeed of the cleverest man I ever met. I do not think I need detain you on the report, for it simply goes through the balance-sheet, and mentions the fact that I have been elected Chairman. I will now proceed to the balance-sheet. The first item I will deal with is the capital account, and I call attention to that to show you how it is that we are enabled to make the dividend we recommend. We have an authorised capital of £200,000, a subscribed capital of £100,000, and a paid-up capital of £20,000, so that, in plain language, we have good credit and a small capital to pay a dividend on. I cannot better illustrate that than by our present dividend, which is £6,000, or sufficient on our authorised capital to pay only 3 per cent., on our subscribed capital 6 per cent., and on our paid-up capital 30 per cent. Therein is the great secret of our success, as I said before. The next item is the reserve fund of the holders of the founders' shares. That is invested by the Directors in a manner which, they think, will ultimately turn out to the advantage of the founders. The reserve fund of the Ordinary shareholders is invested in the business of the Company. There is a loan account of £20,000, but there is a loan on the other side of the balance-sheet of £14,000, so that there is a loan account of only between £5,000 and £6,000. The sundry creditors are the usual creditors for the time being, most of whom would be paid within a fortnight. The item of "unclaimed dividends" speaks for itself, as does also the item of profit and loss account. I will mention the dividend further on. I will now turn to the other side of the balance-sheet, and the first item there is "investments at cost." We have placed it in that manner for the sake of our convenience, but we had made an estimate, and as I know that the item of "investments at cost" is always likely to provoke an inquiry in the shareholders' minds whether they are worth that money or not, I can assure them that our investments are worth that price, even at the present depressed quotations. The "loan against security" is more a matter of book-keeping, there is a liability attached to it, which, however, is fully covered. "Sundry debtors," amounting to £1,356, are all good. "Cash on current account at bankers" speaks for itself; and the "founders' reserve fund" I have already spoken of. Passing to the profit and loss account, "the general charges, including Directors' fees and their additional remuneration, &c.," have been £3,164 for the past year. In our first report that item only amounted to £1,000, but it is *not* a subject of congratulation that it should be £1,000. It is a subject of congratulation to the shareholders when this item mounts up, because when it does it means that more business is doing, and also that we, your Directors, get an additional remuneration—a certain percentage on the profits—after you have received your 10 per cent. Therefore, it is to your distinct advantage to see that item mount up. The interim dividend you have already received, and the balance is £5,928, making, united with the £137, the balance from 1892, the sum of £6,065 which we now have available for distribution. I do not think I will occupy you any longer. I might call your attention, however, to the fact that in the last three years, during which we have been established, we have returned you nearly 12s. 6d. out of every sovereign you invested, and we have also put to the reserve fund 10s. We have therefore earned nearly 22s. 6d. already for every pound you have invested in this Company. I think you will agree with me and the Board that we have reason to be proud of our success, and I hope you will say that the Directors have deserved the remuneration they receive. Of course, if we have a good prosperous year, we should earn more dividend, but in bad years we may earn less, and I should like to give you this word of warning—that the mere fact of your receiving 25 per cent. per annum shows that, to a certain extent, it is more or less speculative, and when a bad year comes I hope that you will not reproach us. I do not anticipate a bad year, but one might come. If we have prosperous years the public might be inclined for electrical investments. We have one which we shall bring out, and I believe that even in these depressed times it will go down well, but I am perfectly sure that in good times it would be subscribed for four or five times over. I will now move "That the report of the Directors and the statement of accounts to May 31, 1893, with the appropriation of the surplus profits as proposed, be and the same are hereby received and adopted."

Mr. J. B. BRAITHWAITE, Junr.: I have great pleasure in seconding the adoption of the report and accounts. I can only endorse what the Chairman has said—that we believe our balance-sheet is a thoroughly sound one, especially the item of "investments at cost," which is usually the item in which, if there is anything unsound, it is wrapped up. I can thoroughly endorse what the Chairman says, however—that we believe our investments to be worth to-day, even in these depressed times, all that we gave for them, and that we could realise them for fully the sum at which they stand in the balance-sheet.

The CHAIRMAN then put the motion, and it was carried unanimously. He afterwards proposed the following resolution:—

"That a dividend at the rate of 30 per cent. per annum for the half-year ended May 31, 1893, making, with the interim dividend of 10 per cent. paid for the six months ended November 30, 1892, 25 per cent. for the year, be and the same is hereby declared on the capital paid up on the Ordinary shares, that a dividend of £30 be declared on each Founders' share, and that the respective dividend, be paid on July 1, 1893."

The Right Hon. Lord CLONCURRY briefly expressed his pleasure in seconding the resolution, which was carried unanimously.

Mr. B. H. VAN TROMP: It is my pleasing duty to propose the re-election of Mr. Joseph Bevan Braithwaite, jun., and Lord Cloncurry as Directors of this Company. I think you have special evidence in the balance-sheet before you and in the admirable speech from the Chairman that your business is thoroughly well-conducted by your Board, and I will ask you, therefore, unanimously to re-elect these two gentlemen as Directors.

The MANAGING DIRECTOR (Mr. Emile Garcke) seconded the motion, which was unanimously adopted.

A resolution was afterwards passed re-electing Messrs. Rait and Kearton, auditors of the Company, for the year ending May 31, 1894, at a fee of 50 guineas.

Mr. KEARTON, in acknowledging the re-election of his firm, said he hoped it might be his pleasing duty in the future to audit such accounts as those now submitted to the shareholders. He had received all the information he had asked for, and had been met all through with the greatest consideration. He had sometimes thought he had been regarded as a bother, but his desire had been to get at the bottom of everything in connection with the accounts.

The proceedings then terminated.

Norwich Electricity Company (Limited).

The second ordinary general meeting of this Company was held on the 17th inst., at the office, Queen-street, Norwich, Mr. F. W. Harmer presiding.

The CHAIRMAN, in moving the adoption of the report, said the Board were glad to announce that the works would be in full working order in a short time. The Directors had not been ready to start before, because it was a case where, had they taken more haste, it would certainly have resulted in less speed. They determined, before they spent the money

Digitized by Google

which had been entrusted to them, to make every inquiry that was possible in order to ascertain, from the experience of other places, the best way of dealing with the difficult problem they had to solve. That it was a difficult one was shown by the fact that the Corporation had determined, after very careful consideration, to leave the question of electric lighting alone. There was no such general consensus of opinion among electricians, either as to the best principal of producing and distributing electricity or as to the most suitable machinery and apparatus to use for that purpose, that would have justified the Directors in proceeding otherwise than with the greatest caution. There was hardly any detail to which they had not given the closest personal attention, and they had taken no important step without getting the best scientific advice within their reach. The arrangement which the Directors had made with Messrs. Laurence, Scott, and Co., to carry on and develop the business of electric lighting in the city until the Company was ready to start, had worked well. Since the beginning of the present year the number of lamps installed had nearly doubled, and thus the Company would commence its operations with a guaranteed income for the first year. Although the work of the last few years had cost them a great deal of labour and anxiety, the Directors did not at present ask for any remuneration, as their great desire was to make the Company a success, but when it became so, as he had no doubt it would before long, they felt they might leave it to the shareholders to vote them such a sum as they might think they had earned. Replying to questions, the Chairman said that the normal price for the electric light in Norwich was 8d. per unit, and he doubted whether it could be produced here, at any rate at first, at less than that figure. The Directors had, however, at the suggestion of Messrs. Laurence, Scott, and Co., determined to try the experiment, which he believed had not been adopted elsewhere, of charging half-price to any person who desired to take the current after the general demand for the light had ceased. One of the great expenses of electric lighting was that of getting up steam; when the steam was once got up it cost comparatively little to run the machinery an extra hour, and they were willing that all their customers should share in the advantage of getting in this way light at a reduced price which it would cost them less to produce.

The report having been adopted, the retiring Directors and auditor were re-elected, and the proceedings terminated.

The Directors' report included the following:—

"After much inquiry as to the respective merits of the different systems of electric lighting, and their adaptability to the conditions of Norwich, including personal visits to many of the stations which are at work successfully in different parts of the country, the Directors finally arranged with Messrs. Laurence, Scott, and Co., of this city, to carry out, on advantageous terms, plans which they had prepared with the assistance of Prof. Henry Robinson, C.E., the consulting engineer of the St. Pancras Vestry. The Directors have purchased, on favourable conditions, an admirable site for their central station, near Duke's Palace Bridge, which fulfils all the conditions necessary for the economical production and distribution of electrical energy, and is large enough to give ample room for future expansion. Buildings have been erected on this site, and the necessary machinery is now being laid down in them. In selecting and purchasing this machinery, and in carrying out the works generally, the Directors have endeavoured to take advantage of the experience of towns which were earlier in the field, and they hope, as a result of this, that when it is completed the shareholders will find themselves in possession of apparatus of the newest and most efficient kind. The Directors believe the work of the contracting engineers has been carried out in a careful and substantial manner. Messrs. Laurence, Scott, and Co., having been for some years supplying electric light and power in the city, the Directors thought it desirable in the interest of the Company to arrange with them to continue to do so until the Company was ready to start working. The experience of other towns shows that as soon as electrical stations are started the demand for light, &c., rapidly increases, and the inquiries which the Directors are now receiving are such that they believe that their present machinery will not long be sufficient to supply the needs of their customers. They propose, therefore, to offer to the public a portion of the shares at present unissued."

Electricity Supply Company for Spain (Limited).

The fifth ordinary general meeting of the shareholders of this Company was held on Monday at the offices, St. Helen's-place, Lord Castletown of Upper Ossory, in the chair. A correspondent sends us the following account of the proceedings:—

The report presented by the Directors for the year 1892 stated, *inter alia*, that the balance of the debt due to Messrs. C. de Murrieta and Co. (Limited) has been liquidated all but a small sum of about £220 by the issue to the receivers and managers of the £40,000 Second Mortgage Debentures. During the year a large sum has been spent on improving the position of the Company by further canalisation, and by the installation of meters and converters, which has been found necessary owing to the increased demand for electricity. The profit and loss account shows a net profit in Madrid of £7,084. 2s. 5d., as against a loss of £1,229. 10s. 7d. in 1891. Including interest on debentures and London expenses the balance at the debit of profit and loss is £2,055. 13s. in 1892, as against £8,457. 6s. 7d. in 1891. Early in the present year a change was made in the management at Madrid, and Mr. H. E. C. Clarke was appointed to carry on the affairs of the Company in Madrid in the place of Señor Gonzalez. Mr. Chisholm was appointed Chief Engineer of the Company in the place of Mr. Robinson. Mr. Chisholm was the engineer by whom the electric light station and all its machinery was erected, and he has had considerable experience in the working of the particular system in use. Many economies have been effected in the general management of the business both in the office and in the works, by a reduction in the staff, and by a considerable saving in the quantity of stores used.

The CHAIRMAN referred with satisfaction to the improvements in the Company's business, which he showed by comparing the working one year with another, and also month by month. There had been a large increase in the gross revenue, in the number of lamps placed, and in the number of consumers. The growth of their business had, in fact, been so great that it had become necessary to issue the £25,000 Prior Lien Bonds, which they were now placing in order to meet the increased demands upon them. Referring to the accounts, he stated that there were certain exceptional items last year, amounting to £1,300, and if these had been eliminated the net loss would have been reduced to £700. With reference to the present year, the current sold during the first four months showed a very large increase as compared with the corresponding period of 1892, and since the last report the number of lights installed had been largely added to. It had, therefore, become absolutely necessary to expend further capital in enlarging the works and providing further plant. He concluded by moving the adoption of the report.

Mr. E. F. G. HATCH seconded the motion, which was adopted: and resolutions were afterwards passed confirming the election as a Director of Mr. John Annan to fill the vacancy caused by the retirement of Mr. Germaine; re-electing the retiring Director, Mr. Alfred George Gillingham; and appointing Messrs. Deloitte, Dever, Griffiths, and Co., chartered accountants, as auditors to the Company, Messrs. Broads, Paterson, and Co., the late auditors, having retired in consequence of the election of Mr. Annan as a Director, that gentleman being a partner in their firm.

West African Telegraph Company (Limited).

The following is the report of the Directors to the eighth ordinary general meeting to be held at Winchester House, on Thursday, July 13th, at 2:30 p.m.:—

The Company's revenue for the twelve months ended December 31, 1892, amounted to £60.922. 14s. 2d., against which £20.018. 14s. 8d. is charged for ordinary expenses, £13,964. 3s. 7d. for expenditure relating to repairs of cables, &c., and £802. 10s. 3d. for income-tax, leaving a balance of £26,137. 5s. 8d. From this amount is deducted £23.726. 15s. 10d. (being for interest on debentures £13.060. 2s. 6d. and for sinking fund £10,666. 13s. 4d.), leaving a balance of £2,410. 9s. 10d., which it has been decided to carry forward.

The large increase in the expenditure for repairs of cables is mainly due to the breaks that have occurred in our São Thomé-Loanda section, off the River Congo. This cable is now being diverted beyond the influence of the currents caused by the river. Although this operation will involve heavy expenses, after mature consideration this course has been decided upon as being the most economical means of avoiding the constant interruptions which have occurred at the mouth of the Congo.

It will be seen from the accounts that we have made a further loss on exchange of £8,044. 10s. 1d., for the year under review, which is chiefly owing to the continued depreciation of Portuguese currency. Negotiations are still being carried on with a view, as far as possible, to minimise the loss in future transactions.

On reference to abstract C of the report, full details will be found of the numerous repairs effected during the year. The several sections of the Company's cables are (with the exception of the interruption named) in good working order.

We record, with regret, the decease of our colleague, Sir James Anderson. Mr. John Denison Pender has been elected to fill the post of Managing Director thus vacated, and Mr. John Cambrook has been appointed secretary in the place of the late Mr. William Payton. The Director who retires by rotation is Sir Henry C. Mance, C.I.E., M.Inst. C.E., who, being eligible, offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co. also retire, and offer themselves for re-election.

United River Plate Telephone Company (Limited).

The following report of the Directors of this Company for the year ended March 31st last, is to be presented at the seventh ordinary general meeting, to be held at Winchester House, E.C., on Tuesday, July 4th, at 12 o'clock:—

After deduction of expenses in the River Plate, loss on exchange, debenture interest, and other London charges, the Directors are pleased to report that the year's working has enabled them to write off £768. 7s. 8d., the balance of taxes suspense account, £2,728. 12s. 9d. for bad and doubtful debts, and to carry £3,000 to depreciation and renewal fund. There then remains a balance of £540. 3s. 3d., increased by £365. 9s. 9d., brought forward from the previous year to £905. 13s. The capital expenditure for the year amounted to £5,394. 10s. 9d., and the working expenses in the River Plate were, at par of exchange, £57,668. 19s. 2d., against £53,618. 9s. 8d. in the previous year.

Since March 31st last the business of the Company has kept pace with the general improvement in affairs in the Argentine Republic; it is expected that this improvement will continue and that the Company will soon be in a position to resume payment of dividends.

The Board desire to express sincere regret at parting with their esteemed colleague, Mr. J. Owen Unwin, who, in order to effect a reduction in the number of Directors, which has been for some time contemplated, has resigned his seat at the Board. Under the Articles of Association, Mr. Frank W. Jones and Mr. Frederick Green retire, and being eligible offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also retire.

Electric Construction Corporation (Limited).

An extraordinary general meeting of this Company will be held at the Cannon-street Hotel, E.C., on Wednesday, July 5th, at three o'clock, for the purpose of considering, and, if thought fit, passing the following resolutions as special resolutions, viz. :—

1. That it is desirable that the Corporation be reconstructed, and that with a view to such reconstruction the Corporation be wound up voluntarily.

2. That the Liquidators be, and they are hereby, authorised to consent to the incorporation of a Company (hereinafter called "the new Company") with the name of "The Electric Construction Company (Limited)," or such other name as the Liquidators may approve.

3. That the capital of the new company be £400,000, divided into 150,000 Ordinary shares of £2 each, and 50,000 Seven per Cent. Cumulative Preference shares of £2 each.

4. That the Memorandum and Articles of Association of the new Company be in such form as the Liquidator shall approve.

5. That, in accordance with the provisions of Section 161 of the Companies Act, 1862, the Liquidators be, and they are hereby, authorised to transfer to the new Company, as from July 1, 1893, all the assets and undertaking of the Corporation, upon the terms that the new Company shall pay or satisfy all the debts and liabilities of the Corporation, including the costs of the winding-up and reconstruction, and shall issue to the holders of the First and Second Mortgage Debentures of the Corporation First and Second Mortgage Debentures of the new Company of the same nominal amount, and carrying the same rate of interest as the First and Second Mortgage Debentures of the Corporation, and ranking as first and second charges respectively upon the undertaking, property, uncalled capital, and assets of the new Company, such First and Second Mortgage Debentures to be in such form, and to be secured by such Trust Deeds as the liquidators shall approve, and upon the further terms that the new Company shall issue to the Liquidators, or as they may direct, 120,000 fully-paid Ordinary shares and 14,630 fully-paid Preference shares of the new Company.

6. That the 120,000 fully-paid Ordinary shares of the new Company be distributed as follows :—

(*a*) To the holders of Income Bonds of the Corporation two shares for every £10 of Income Bonds in satisfaction of such bonds.

(*b*) To the holders of Founders' shares of the Corporation two shares for every Founders' share.

(*c*) To the holders of Ordinary shares of the Corporation two shares for every Ordinary share of the Corporation.

7. That the 14,630 fully-paid Preference shares of the new Company be distributed among the holders of the Preference shares of the Corporation in the proportion of five fully-paid Preference shares of the new Company (£10) for every fully-paid Preference share of the Corporation.

8. That the Liquidators be, and they are hereby, authorised to enter into such agreements with the new Company or a Trustee for the new Company, and generally to do all such acts and things as they may think expedient for carrying the reconstruction into effect.

Notice is also given that if the above resolutions are passed they will be submitted to a second extraordinary general meeting to be called, at which meeting the Liquidators will be appointed.

The following circular has been issued to the shareholders of the Company :—

"Since the last general meeting your Directors have carefully considered the best means of placing the Corporation in a sound commercial and financial position, and they are glad to be able to report satisfactory progress in this direction. Important reductions have been made in the general expenses, the Directors have reduced their remuneration, and such further economies as will not interfere with efficiency will be introduced as opportunity offers.

"During the past year seven Directors have vacated their seats, and three new Directors have been appointed, and the Board has thus been practically reconstituted. The Directors, recognising the necessity of a commercial manager for the economical and efficient administration of the business, consider themselves fortunate in having secured as Managing Director Mr. Emile Garcke, whose experience and success as manager for several years of the Brush Electrical Engineering Company specially qualify him for the position. Mr. James Gray has recently been appointed Secretary. The Directors have also much pleasure in reporting that the important engineering and manufacturing contracts carried out by the Works Director, Mr. Thomas Parker, have not only given entire satisfaction but established for the Corporation a high reputation for excellence of design and workmanship.

"In accordance with the views expressed at the general meeting, it has been the duty of the reconstituted Board to determine, according to the best of their judgment, whether the capital of the Corporation is adequately represented by its assets, and after careful and anxious deliberation the Directors have come to the conclusion that a re-arrangement of capital by reconstruction is both expedient and necessary. This, they are of opinion, can be most advantageously carried out by the formation of a new company with reduced capital. As a consequence of the reconstruction, future profits would be applicable to payment of dividends, instead of to making good the deficiency on capital account. [Here follows particulars of the scheme of reconstruction as set out in Resolutions 2 to 8 above.] The statement below shows the present capital of the Corporation and the capital of the proposed new Company to be issued in exchange.

"The works of the Corporation at Bushbury are generally admitted to be the best of their kind in the kingdom, and the plant is specially adapted to the business, and is in very good condition. The patents owned by the Corporation are valuable, and the electro-chemical patents taken out by Mr. Parker and the technical staff especially give good promise of profitable results.

"The ability of the Corporation to carry out large and important contracts has been shown by the successful completion of the Liverpool Overhead Electric Railway, of the South Staffordshire Electric Tramways, and of numerous electric lighting contracts and other applications of electricity in London and the provinces.

"Having most carefully considered the whole position, the Directors are of opinion that the capital of the new Company will be fairly represented by its assets, and that the proposed reconstruction deals equitably with the various interests, and places the Company in a strong position for doing such an amount of profitable work as may be reasonably expected to yield a satisfactory return upon the reduced capital.

"By reason of the reorganisation of the business, which has been in progress for some months past, it is impracticable at present to give the result of the working during the portion of the year which has elapsed: but perhaps the best evidence of the confidence of the Board in the future of the Company is that several of its members have since the last general meeting acquired shares, advanced money, or otherwise supported the Corporation to an amount exceeding £30,000.

"The Board attach much importance to having the support of every shareholder.

"On behalf of the Board,
"DANIEL COOPER, Chairman.

"Worcester House, Wallbrook, E.C., June 26, 1893."

STATEMENT SHOWING THE CAPITAL OF THE ELECTRIC CONSTRUCTION CORPORATION (LIMITED) AND THE CAPITAL OF THE PROPOSED NEW COMPANY.

NEW COMPANIES, STATUTORY RETURNS, &c.

NORTH-EASTERN TELEPHONE COMPANY (LIMITED).—This Company was registered on the 20th inst. with a capital of £1,000, in £1 shares, to carry on the business of a telephone, telegraph, and electric light, heat and power supply company, and to manufacture, construct, purchase, or otherwise acquire, lay down, carry out, work or otherwise turn to account cables, wires, lines, stations, exchanges, reservoirs, accumulators, lamps, meters, and anything that may be required for or capable of being used in connection with the transmission of messages or with the generation, distribution, supply, accumulation and employment of electricity. The subscribers (with one share each) are:—G. H. Coates, 33, Mosley-street, Newcastle; A. O. Challoner, Benwell Lodge, Newcastle; C. Thompson, 9, Dean-street, Newcastle; G. H. Wear, Post Office-chambers, Newcastle; William Cowell, 9, Pilgrim-street, Newcastle; S. Price, 161, North-street, Newcastle; and T. Telford, 18, Wharncliffe-street, Newcastle. The number of Directors is not to be less than three, nor more than seven.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY LIMITED).—This Company has been registered with a capital of £300,000, in £1 shares, to carry on in the United States of America, England, and elsewhere, and particularly in the Territory of Utah, U.S.A., the business of a gas and electric lighting company in all its respective branches, and as manufacturers of and dealers in every description of apparatus and appliances for the same. The first signatories to the Memorandum of Association are:—C. Hanley, 112, Bishopsgate-street, E.C.; J. B. Braithwaite, 27, Austinfriars, E.C.; C. J. Hamilton, Glenridge, Virginia Water; F. H. Leslie, 251, Winchester House, E.C.; T. Salt, Weeping Cross, Stafford; J. Bousted, 34, Craven-street, W.C.; H. Noel, 17, Westbourne-terrace, W. There shall not be less than three nor more than seven Directors; the first are to be elected by the signatories to the Memorandum of Association.

VALVELESS GAS ENGINE SYNDICATE (LIMITED).—This Company was registered on the 19th inst. with a capital of £15,000, in £10 shares, to acquire, develop, and turn to account certain patents, patent rights, inventions, &c., relating to gas and vapour engines, and, with a view to such acquisition, to enter into and carry into effect agreements with Joseph Day, of Bath, and with Easton and Anderson (Limited).

ARCAS PLATING COMPANY (LIMITED).—A petition for the winding-up of this Company has been presented, and is down for hearing at the Royal Courts of Justice, Strand, on July 8th.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—A petition for the winding-up of this Company has been presented by Sir Daniel Cooper, and is down for hearing at the Royal Courts of Justice, Strand, on July 8th. Any person who intends to appear on the hearing of the petition must communicate with Messrs. Linklater, Hackwood, Addison, and Brown, 2, Bond-court, Walbrook, E.C, not later than July 7th.

ELECTRICAL SUPPLIES AND FITTINGS COMPANY (LIMITED).—Mr. Justice Vaughan Williams on the 15th inst. ordered that the voluntary winding-up of this Company be continued, but subject to the supervision of the Court.

PIKE, HARRIS, AND CO. (LIMITED).—The statutory return of this Company, made up to and filed on May 11, 1893, records the fact that out of a nominal capital of £30.000, divided into 1,400 "A" and 4,600 "B" shares, of £5 each, 1,218 "A" and 3,600 "B" shares have been taken up. The "B" shares have been issued as fully paid, while the full amounts have been called and all calls paid (£6,090) on the "A" shares.

VOLTA ELECTRICAL COMPANY (LIMITED).—A meeting is to be held at Messrs. Rycroft and Bellhouse's, 2, St. Peter's-square, Manchester, on July 28th, at 3 p.m., to receive an account of the winding-up of this Company.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—When the annual return for 1c93 of this Company was made up, 64,242 £15 and 96.258 £7. 10s. shares were taken up, the full amount called, and all calls paid, the amount resulting therefrom totalling £1,460.565 (which includes £565 paid on 75 forfeited shares. Share warrants to the value of £1,725, comprising five shares each, and to the value of £225, comprising one share each, are outstanding, no shares having been surrendered or issued since last summary.

WESTINGHOUSE ELECTRIC COMPANY (LIMITED).—The annual return of this Company for 1893 shows that with a nominal capital of £600,000, divided into an equal number of Preference and Ordinary shares of £10 each, 18,955 Preference and 20,000 shares have been taken up, of which 15.800 Preference and 20,000 were issued as fully paid to the vendor Company. Upon 1,835 Preference the full amount per share has been called, while upon the remaining 1,320 shares a call of 10s. per share has been made, resulting in the total payment of £19,010.

WILLANS AND ROBINSON (LIMITED).—The annual return of this Company made up to April 26th, and recently filed, shows that out of a capital of £200,000 in £50 shares, 2,214 fully paid, 58 £5 paid, and 11 £25 paid shares were taken up. 980 shares have been issued as fully paid, and upon the remaining shares calls to the extent of the amount given as part of their title have been paid, the payments being £62,265.

EDINBURGH.—An extraordinary general meeting of the Edinburgh Electric Supply Corporation was held in Edinburgh this afternoon for the purpose of winding-up. The Company was established with a capital of £33,000, on the anticipation that they would be entrusted with the lighting of the city. The Corporation has resolved to take the lighting into their own hands. A resolution for winding-up was agreed to.

CITY NOTES, &c.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—Coupons No. 11 of the First Mortgage and No. 6 of the Second Mortgage Debentures of this Company will be paid (less income-tax) by Parr's Banking Company and the Alliance Bank, Bartholomew-lane, E.C., on and after July 1st.

CENTRAL LONDON RAILWAY COMPANY.—A special general meeting of the proprietors of this Company was held on Tuesday, at 30, St. Swithin's-lane, E.C., "for the purpose of submitting 'an Act for incorporating the Waterloo and City Railway Company, and for empowering them to construct an underground railway from near Waterloo Station to Mansion House, City, and for other purposes.'" Mr. F. A. Lucas presided, and said the meeting was convened in accordance with the Standing Orders of the House of Lords. The Waterloo and City Bill contained a clause enabling both Companies to enter into a working agreement, and it was therefore necessary that the proprietors should formally approve the Bill. A formal resolution approving of the Bill, subject to such additions, alterations, and variations as Parliament might make therein, was carried unanimously without discussion.

CHATHAM, ROCHESTER AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The adjourned meeting of the shareholders of this Company was held last week, under the presidency of Mr. J. S. Benton. It will be remembered that the first meeting was held on March 21st, when a resolution to approve of certain contracts between the Company and its Chairman (Mr. Jasper), whereby Mr. Jasper agreed to supply and erect plant, works and machinery for the Company for the sum of £18,630, payable in 3,726 fully-paid shares of the Company, was discussed. As something had to be done towards starting the works (or the Provisional Order obtained by the Company would be revoked) and as the Company had been unsuccessful in borrowing the necessary money at 6 per cent. interest, the Chairman undertook the works himself and had actually spent £9.315. Some shareholders were disposed to think that Mr. Jasper was driving a hard bargain with the Company in claiming shares worth £18,630 in payment of the amount he had actually spent, but it was pointed out that the work was not finished, and that Mr. Jasper was still liable to pay a considerable additional sum. It was ultimately decided to adjourn the meeting for three months, and at the meeting last week considerable further discussion took place, and it was finally resolved to again adjourn for a week, three shareholders being appointed to confer with Mr. Jasper upon the subject. This conference has since been held, and to understand that arrangements satisfactory to all parties have been come to.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 25th were £765, as against £747 for the corresponding period of last year, being an increase of £18. The total receipts for the half-year amount to £21,799, against £20,132 in the corresponding period of 1892, being an increase of £1,667.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Letters of allotment for the recent issue of 20,000 Preference shares in this Company have been posted.——The Directors of this Company yesterday declared an interim dividend of 3s. 4d. per £10 share, less income-tax, of the first issue of 20,000 Cumulative Six per Cent. Preference Shares Nos. 1 to 20,000 inclusive. The payment is calculated at the rate of 6 per cent. per annum on the respective instalments for the period ended June 30, 1893, and it is payable on July 11th next.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce that, subject to the final audit, the accounts show, after placing about £88.000 to reserve fund, a balance available sufficient to pay at the general meeting on July 13th next the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the Preference shares, less income-tax, and a final payment of 2s. 6d. per share with a bonus of 3s. per share, both free of income-tax, on the Ordinary shares, making, with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ended March 31, 1893. The transfer books of the Company will be closed from July 6th to 13th, both days inclusive.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company on Wednesday declared an interim dividend, for the quarter ended March 31st last, of 2s. 6d. per share, free of income-tax, payable on the 15th prox. The Share Register will be closed from the 7th to the 14th prox., both days inclusive.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LTD).—An extraordinary general meeting of this Company will be held at Winchester House, E.C., on Monday, July 3rd, at three o'clock, "To receive and consider a report of the progress of the Company during the six months ended June 30, 1893; to appoint an auditor or auditors; and to consider the propriety of raising further capital."

JOHANNESBURG LIGHTING COMPANY (LIMITED).—A scheme for the reconstruction of this Company, with a capital of £155,000, is preparing. Ordinary shareholders will receive one share for two, 55.000 Ordinary shares will be exchanged for the 55.000 existing Preference shares and 60,000 shares will go to the subscribers of the £45,000 of working capital, which is needed.

REDRUTH ELECTRIC LIGHT COMPANY (LIMITED).—The Company which was to have been formed for supplying Redruth with the electric light has been abandoned owing to lack of public support. A considerable number of shares were applied for, but not enough to warrant going to allotment.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee appointed Wednesday, the 28th inst., a special settling day in the following:—Crompton and Co. (Limited), £50,000 Five per Cent. First Mortgage Debentures, Nos. 1 to 400 of £100 each, and Nos. A 1 to A 200 of £50 each. The Committee have ordered these debentures to be quoted in the Official List, as well as the following securities of the United Alkali

Digitized by Google

Company (Limited):—289,343 Ordinary shares, Nos. 1 to 18,697 and 29,355 to 300,000; 282,524 Seven per Cent. Cumulative Preference shares, Nos. 1 to 122,195 and 139,672 to 300,000; £2,500,000 Five per Cent. Mortgage Debenture Stock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 23, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,476.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 790.—Vol. XXXI. FRIDAY, JULY 7, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Our readers will remember that an attempt was made some ime ago to establish telegraphic communication between undy Island and the mainland at Hartland point. On this sland there has been for many years an important lighthouse, vhich protects vessels entering the Bristol Channel. A cable was aid in March, 1884, by a small company; and was partly sup-orted by a subsidy of £100 a year from Lloyd's, who under-ook to place a signal station on the island, and partly by a oyalty of two shillings which was levied on each message ransmitted to the mainland. But the apathy of the sailor, vho generally did not care to spend money on signals when nly a few hours' run from port, and the physical evils of a wift tideway and a rocky sea-bottom, soon threw both cable nd company out of working order. The latter was wound p, and the former was hauled up, and sold to Mr. Rogers, vho had undertaken the laying of it. A new cable has ecently been laid, and we learn on inquiry that the work as been done in connection with the extensive Government cheme of coast communication; and that the new cable has een laid between Lundy and Braunton, a point some distance ıside the Barnstaple Bay, whereby it is less exposed to the ffects of rocks and the tidal wash.

There is a general impression that on November 11th next, wing to the expiry of Edison's patent No. 4,576, on the 10th, ne English market will be open for the sale of glow lamps. o what extent certain subsequent patents for details of onstruction or for lampholder fittings can be avoided, remains o be seen; but these matters have doubtless received the areful attention of importers. The subject of the manufac-ure of glow lamps has been devoid of all interest to English lectricians for many years, seeing that even experimental work s prohibited under the Patent law, and the number of nen outside the Ponder's End factory who know anything bout it is very limited. Of these few Mr. Gilbert S. Ram is ne who has had considerable practical experience both in the nited States and in this country; and this week we begin a eries of articles which form part of a book on "The Incan-lescent Lamp: its Manufacture and Use." As this book vill shortly be published we shall be unable to print any con-iderable portion of it in full in our columns, as was done with Prof. Ewing's "Magnetic Induction in Iron and other Metals," or Prof. Fleming's "Alternate Current Transformer," but selections will be made with the view of giving a general idea of the processes of manufacture and the principles which underlie them.

Electrical research should receive a healthy stimulus, and scientific progress ought to be accelerated to some extent, by the complete set of laboratories which has recently been built under the auspices of the Société International des Electriciens in Paris, and which was recently opened by M. Terrier, the Minister of Commerce and the Colonies. The institution includes ten laboratories and a dynamo room, in the latter of which there are a gas engine and triple expansion steam engine. The equipment of the laboratories seems to be very perfect, and the ten rooms are devoted severally to wire testing, cable testing, calibrating voltmeters, measurements of potential, electro-chemistry, calibration of ammeters, photometry, measurements of capacity, standardising resistance coils, besides an accumulator room containing various types of cells. The entire *ensemble* of the institution affords an additional instance to the many we already have of the thoroughness and vigour with which technical progress is pushed forward in France and other continental countries.

The representation of abstract truth and of theory in science, by the aid of diagrams and models, is one which is helpful alike to investigators, teachers, and scholars. In another column we publish an interesting abstract from the catalogue of the Mathematical Exhibition, in which Prof. Boltzmann attaches prime importance to Maxwell's models in the deduction of the Maxwell theory of electromagnetism. In this we, however, cannot entirely agree; for it can never be true that the amount of concrete truth contained in a model can be greater than the amount of pure or abstract truth which was put into it in its original conception. A model, in so far as it is such and nothing else, is merely a tangible presentiment of one or more ideas in the mind of the person who designs it. Hertz's praise was rightly bestowed, not because the models contained more than the equations they represented, but because Nature is always deeper than our profoundest conception of her, and because the closer the equations are to natural truth the more they must reflect the deeper truths of Nature.

To apply the elaborate algebra, which Mr. Rimington contributes this week, to the unpretentious little cell-testing device of Major Holden is to break a butterfly upon the wheel. The instrument was not submitted to us as an apparatus for

Digitized by Google

measuring the internal resistance of a battery, and we were careful, both in the title and in the first sentence of our article on it a fortnight ago, to suggest that it was suitable for testing the condition of a cell rather than for making an accurate scientific determination of a quantity, which is, after all, purely hypothetical. Given a cell, which, admittedly, polarises when it is discharged; to make an examination which eliminates polarisation, is to make an examination in which practical considerations are ignored. "Why, you must have been taking it out in the rain and getting it wet!" said the shopkeeper, in *Punch*, to the disgusted purchaser of an umbrella.

It is often necessary to draw a hard line between scientific and practical modes of work or thought. This question of internal resistance of batteries is a good example. A knowledge of the internal resistance of a battery is only of importance to most users of batteries, when it is accompanied by a statement of the relation between the resistance and the current given by the cell. This relation nobody seems to trouble themselves about, partly, perhaps, because a third factor, the condition or age of the cell, must be taken into account. In theoretical investigations of electro-chemical action and of electromotive force, as distinguished from difference of potential, true internal resistance must be accurately measured, although it is a quantity which really exists only as a limit. We, therefore, welcome Mr. Rimington's contribution to this subject. His criticism of the accuracy of the Holden cell tester requires a word of comment. It is true that an error of one per cent. in a reading produces large errors in the result, but a delay of a second or so will produce quite as large an error with most primary batteries, due to a change, not only in the readings, but in the quantity to be measured. In checking Mr. Rimington's comment on the readings of the E.C.C. cell, we find there is a misprint in the second reading on page 200, and, on examining the original diagram sent by Major Holden, the real value seems to be about 1·36.

We have tried the Holden cell tester on a few different cells, and find it to be very easy to use. After a little practice it would not be difficult to form an opinion of the condition of a cell from a mere glance at the two positions of the needle without having recourse to either diagrams or calculations. The cells we tested were all old, and are used for lighting a lady's house in Kensington. A large "Law" Leclanché had an internal resistance of 0·51 ohm, a small "Henry" dry cell 0·55 ohm, and a small Hellesen cell 0·54 ohm. It should be observed that while the load on these cells is severe while it lasts, they are not used every evening; the lady is about four years old, and the house is a doll's house.

Standard Wave-Lengths.—The results of ten years' research on wave-lengths, which has been made by Prof. Rowland and Mr. Jewell, are now published in the form of a comprehensive table in the July number of the *Philosophical Magazine*.

Personal.—Mr. J. T. Sheldrick, who was for many years in charge of Messrs. Easton and Anderson's drawing office, has taken offices at Mansion House-chambers, 11, Queen Victoria-street, E.C., where he is practising as consulting engineer.

Cable Interruptions—	Interrupted.
Paramaribo—Cayenne	April 15th.
St. Thome—Loanda	May 30th.

Melbourne.—The inhabitants of this city have been promised by the City Council that one half of the city shall be illuminated with the electric light in six months, and that within 12 months electricity will entirely supersede gas for street lighting.

Royal Institution.—At the last general monthly meeting further donations to the fund for the Promotion of Experimental Research at Low Temperatures were announced. Mr. Ludwig Mond contributed £500, Mr. Robert Hannah £50, besides three other donations of £21 each.

The Mathematical Exhibition.—This exhibition of models and other works of interest connected with abstract and theoretical science, which it was originally intended to hold at Nuremburg last year, will be held at Munich next September. The Exhibition is under the auspices of the Association of German Mathematicians.

Buda-Pesth Electric Tramways Company.—This Company carried in 1892 14,000,000 passengers as against 8,500,000 in 1891; receipts increased nearly 50 per cent., and stand at 766,000 florins; a dividend of 7 per cent. was paid, and 28,000 florins placed to reserve. The remaining capital is to be issued at 150, or 50 per cent. premium.

The Value of H.—The new unifilar magnetometer, at the Kew magnetic Observatory, has during the past year been compared with the older instrument. The mean of the monthly values of the horizontal component of the earth's magnetic field made with this instrument is 0·18288, which is 0·0023 greater than the mean given by the old instrument.

City and Guilds of London Institute.—The Matriculation Examination of this Institution will be held on September 19-22nd next; and the Entrance Examination to Finsbury College on the 29th of that month. Particulars of these examinations, and of the courses of lectures and practical instruction will be found in our advertisement columns.

Glasgow and West of Scotland Technical College.—Henceforth Prof. Jamieson will devote his attention exclusively to electrical engineering. The subject of mechanical engineering is to be taught by a new professor, whose chair is to be that of "Steam, Steam Engines, and other Prime Movers." For the chair there were 24 applicants, of whom Mr. W. H. Watkinson has been selected.

Meteorology in Wales.—Sir Edwin Watkin has placed a telephonic wire between the summit of Snowdon and the Post Office at the vale of Gwynant, on the picturesque slope of which the chalet stands. The service was opened on the 6th inst. in celebration of the Royal wedding. Daily reports of the state of the weather on Snowdon will be furnished to the Meteorological Department.

Lightning.—A heavy thunderstorm at Leeds during the past week completely interrupted the telephone service. Near Leicester a man was killed by a lightning flash; but, quite the reverse of what usually happens, his watch was not stopped. The man's clothing was saturated with rain, which may account for the safety of the timepiece. At Gainsboro' a telephone pole was shattered.

Electricity in Mining.—At the last meeting of the Mining Association of Ecos, the Director of Collieries at Logamba (Mr. Weir) described an electric transmission plant for working the pumps and hauling machinery at the mines. The output of the generator is 200 amperes at 2,000 volts, and an electric motor of equal power, placed at the pit's mouth, works the machinery. The operation of the electric plant gives great satisfaction.

International Electrical Congress at Chicago.—Prof. H. S. Carhart, Honorary Secretary of the Chicago World's Congress of Electricians, informs us that the following have promised to read Papers at the Congress:—Mr. W. H. Preece—"Signalling Through Space by Means of Electro-Magnetic Vibrations;" Prof. W. E. Ayrton—"The Variation of P. D. of the Electric Arc with Current, Thickness of Carbons, and Distance Apart."

Digitized by Google

Lightning Protectors in Powder Magazines.—A series of articles on the protection of magazines and explosives factories from lightning, is now appearing in our contemporary, *Arms and Explosives*. In the current number a "cheap earth," invented by Dr. Mann, is one of the various useful things described. This "earth" is composed of lengths of stranded cable, with the strands frayed out and led, like a fibrous root, in all directions into the soil.

Hutin and Leblanc Alternate-Current Motor.—We believe that the very latest type of motor which has been invented by these engineers may be adapted to ordinary alternate-current mains, without the use of condensers. It is claimed that this machine possesses all the good qualities of a continuous-current motor, the effects of self-induction having been prevented by the use of graduated brushes coupled to non-inductive resistances, combined with a form of armature winding of the Pacinotti-Gramme type.

Electric Light Plants in Switzerland.—In the *Annuaire de l'Association Suisse des Electriciens* for the current year we note a list of the Swiss electric light and power installations of more than 100 16 c.p. lamps or their equivalent. From this table it appears that there are 94 installations in textile factories, 42 in engineering shops, 12 in paper or chemical works, and only one in a printing office. Central stations number 37 and power transmissions 56. Some 13 breweries, 5 railway stations, 5 streets, 76 hotels, and 33 miscellaneous buildings also possess electric light plants.

Obituary.—We are informed of the death of M. Daniel Colladon, of Geneva. Students of physics who have read the older text-books on the subject will remember that M. Colladon, in conjunction with M. Sturm, determined the velocity of sound in water by experiments made on the Lake of Geneva. M. Colladon first lit Geneva with gas in 1843, and was connected with the illumination of other towns by the same agency. He was strongly prejudiced against the electric light, and went so far as to resign his membership of a Geneva club because it was decided to use the electric light.

Conversazione.—More than a year ago we ventured to suggest that as nobody at that time seemed to have a clear idea of what was going to be done at the Imperial Institute, it might be used with great advantage for the *conversazioni* of scientific and other societies. An exceptionally agreeable *conversazione* of the Society of Arts was held at this Institute on Friday last. The gardens were illuminated with oil and gas lamps, and the galleries and hall with electric lights. The opinion was expressed that the use of arc lamps in the gardens would have spoiled the effect of the coloured lights.

Lamp-Circuit Interrupter.—M. Félix Leconte has invented a form of automatic mercury switch, which, when combined with a clock, enables any lamp-circuit to be opened and the lamps extinguished at any desired time. The clock is arranged so as to close a relay circuit, containing an electromagnet, at the prearranged time, and the pull of this magnet is exerted upon a disc of iron which is normally held by springs against a hole in the bottom of the mercury cup. As the mercury forms part of the lamp-circuit, and carries the whole current, the momentary pull of the electromagnet will break the circuit by opening the hole in the cup and allowing the mercury to flow out.

Rapid Transit.—Notwithstanding the recent collapse of certain rapid transit schemes in America, which promised great things at the beginning, there is to be an attempt, we hear, to solve the problem on an experimental line which is about to be erected on Long Island. The wheels of the carriages are to be arranged bicycle-fashion upon a single rail, and a guiding rail will be placed above the carriages. Each carriage is about 60ft. long, and weighs about 3·5 tons. The line is a little more than a mile and a-half in length, and a speed of 100 miles an hour is expected to be attained. About 75 H.P. is to be supplied for this performance, and at full speed the motor armature will make 560 revolutions per minute.

Municipal Amenities.—As the clocks were striking the hour of midnight on the night of May 28th a small army of 400 men armed with picks, shovels and other tools, marched forth from the power house of the Omnibus Cable Company of San Francisco. In less than an hour 10 sets of side poles for electric railway wires were firmly planted in cement, and material was on hand to occupy a hundred more holes which by this time appeared along the curbs. The superintendent of police, however, discovered them, and going to the Mayor secured sufficient police force to stop work. The Company were relying on securing an injunction restraining the city from removing the poles, but the mayor anticipated this and with another large force pulled them all up before breakfast.

Electrically-Controlled Clocks on Lighting Mains.—The Allgemeine Elektricitäts-Gesellschaft send us a note describing an invention of Herr von Hefner-Alteneck, for utilising the central stations in connection with electrically-controlled clocks, on the advantage of which they lay some stress. The invention consists in a clock so arranged that it can be coupled to the lighting mains, and is periodically wound up by electrical means; and that further, once a day, the clock is put right by means of a small and momentary diminution of pressure on the mains, about 6 to 10 volts; this being done at an hour when few lamps are on. It is necessary to keep the pressure right just before the clocks are set daily, but variations at other times do not affect the working. The setting can be done automatically by a standard clock, or by hand, and is said to cost about 4d. per year.

"Drehstrom" Circuit.—Messrs. Siemens and Halske send us some information with regard to a new "drehstrom" transmission of power on which they are engaged, by means of which it is proposed to supply the towns of Elgoibar and Eibar, in the province of Viscaya, in Spain, with electrical energy for lighting and power, derived from the river Deva. A weir has been constructed, by which a fall of 26ft. is obtained, the amount of water coming over being sufficient to supply 300 H.P. The plant is of the usual type, and calls for little notice. The dynamo runs at 120 volts, and the pressure is transformed up to 5,000 volts in the conductors, which transmit the energy to distances of one and three miles to the two small towns. The energy at Eibar is chiefly used for the arms factories, of which several exist here. The undertaking is a private one, and has been started by the owner of the water power.

Scarborough.—A prominent feature of the new electric light works is a chimney of large proportions, about 200ft. high. It is built upon a solid block of concrete, upon a bed of clay. When nearly the maximum height it was found that a settling had occurred in the crown of the arch of the flue. This did not amount, at the point at which it occurred, to more than 2in., though it threw the shaft out of the plumb some 18in. at the top. Work was at once stopped in the structure, and experts were called in to give their advice. They reported that the chimney could be straightened by cutting the courses on the side opposite to that on which the settlement occurred. The Directors of the Company met to consider the report of the experts, and it was stated that in most cases of falls of chimney shafts, the courses had previously been cut in order to straighten them. It was felt that it would be better to run no risks, and it was ultimately decided to pull the chimney partly down and rebuild it again.

The Visible Representation of Lines of Electric Force.—The following experiment for making visible lines of electric force is described by Herr Bruno Kolbe:—Into a flat cylindrical vessel pour purified anhydrous oil of turpentine to a depth of about 2cm., and add some sulphate of quinine. To the rim of the vessel attach two wire springs, adjusted so that the two small metallic balls at their ends dip into the turpentine. Stir the quinine with a glass rod so as to distribute it evenly, and place the vessel on a black cardboard. Join the two wires to the terminals of an influence machine, and turn very slowly. At once the white crystals group themselves so as to form beautiful curves, representing the "lines of electric force." The form of these curves recalls that of the brush discharge of the influence machine. Prof. Weiler, of Esslingen, gives the following experiment:—Prepare a milky mixture by stirring up finely-divided quinine in oil of turpentine. On sending a series of discharges through it a clearance is produced at the positive pole, and the particles cluster round the negative pole, arranging themselves in streamers directed along the lines of

Digitized by Google

force. The phenomenon is analogous to that of electro-deposition. A piece of sheet metal, bent into a cylinder and immersed vertically into the liquid, behaves just like a piece of iron in a magnetic field, creating a new positive and negative pole.

The Methods of Theoretical Physics.—A translation of an important Paper by Boltzmann, upon this subject, appears in the July number of the *Philosophical Magazine*. The Paper originally formed an introduction to the Catalogue of the Mathematical Exhibition, which has been postponed till next September, and deals with the relation of graphic and model represention to physical hypotheses and theory. We quote the following from the section on electricity :—

"In his (Maxwell's) second Paper he goes still further, and from liquid vortices, and friction wheels working within cells with elastic sides, he constructs a wonderful mechanism, which serves as a mechanical model for electromagnetism. This mechanism was mocked at by those who regarded it as a hypothesis in the older sense of the word, and who thought that Maxwell ascribed to it a real existence. This he repudiates, and only modestly hopes '*that by such mechanical fictions anyone who understands the provisional and temporary character of this hypothesis will find himself rather helped than hindered by it in his search after the true interpretation of the phenomena.*' And they were so helped ; for by his model Maxwell arrived at those equations whose peculiar, almost magical, power Hertz, the person most competent of all to judge, thus vigorously depicts in his lecture on the relations between light and electricity : 'We cannot study this wonderful theory without at times feeling as if an independent life and a reason of its own dwelt in these mathematical formulæ ; as if they were wiser than we were, wiser even than their discoverer ; as if they gave out more than had been put into them.' I should like to add to these words of Hertz only this : that Maxwell's formulæ are simple consequences from his mechanical models ; and Hertz's enthusiastic praise is due in the first place, not to Maxwell's analysis, but to his acute penetration in the discovery of mechanical analogies."

An Electro-Chemical Actinometer.—In communications to the *Annales de Chimie et de Physique* and to the *Comptes Rendus*, M. Rigollot has shown that it is possible to make a very sensitive electro-chemical actinometer by employing an electrode of oxide of copper in a chloride, bromide or iodide solution. The electromotive force caused by allowing light rays to fall upon the oxidised electrode may be considerably augmented by giving the oxide a thin film of some colouring substance, such as eosin, erythiosin, sofranine, green malachite, poppy, green crystals, formyl violet, soluble blue, &c., &c. After the plates have been dipped in the colouring matter they may be washed and dried, and even rubbed with filter paper, without losing their augmented sensitiveness. The increase in electromotive force depends, in the case of white light, upon the colouring substance employed. Using an oxidised copper strip 0·3cm. broad by 1cm. long, and a 1 per cent. solution of iodide of sodium, the following results were obtained by causing rays from different parts of the spectrum to fall in succession upon the electrode both before and after immersion in crystal green :—

		λ = 684	650	600	550	500	450	410
Non-sensitised	Scale of divisions.	16	18	80	190	203	200	88
Sensitised		140	760	600	408	380	288	168

It will be seen that the most active rays are those which lie in the part of the spectrum where the absorption band of the colouring solution is found.

Indiarubber Tests.—Lieut. L. Vladimiroff has recently carried out a series of tests at the St. Petersburg Technical Institute with a view to establishing some rules for judging the quantity of vulcanised indiarubber. Most of the tests were of a physical nature. The following, according to the *Indiarubber, Guttapercha, and Electrical Trades' Journal*, were the conclusions arrived at—namely : 1. Indiarubber should not give the least sign of superficial cracking when bent to an angle of 180 degrees after five hours of exposure in a closed air bath to a temperature of 125°C. The test pieces should be 6cm. thick. 2. Rubber that does not contain more than halfit weight of metallic oxides should stretch to five times its length without breaking. 3. Caoutchouc, free from all common matter, except the sulphur used in vulcanising it, should stretch at least seven times its length before rupture. 4. The extension measured immediately after rupture has taken place should not exceed 12 per cent. of the original length of the test piece of rubber. The test piece should be from 3mm. to 12mm. long, 3cm. wide, and not more than 6mm. thick. 5. Softness may be determined by measuring the percentage of ash formed on incineration ; it may form the basis for deciding between different grades of rubber for certain purposes. 6. The vulcanised rubber should not harden under the influence of cold temperature. These conditions are to serve in the establishment of rules governing the introduction of vulcanised rubber into the Russian Navy.

The Utilisation of Small Waterfalls.—In a recent number of *La Lumière Electrique*, M. Chédeville devotes several columns to a discussion of how to make the best use of small waterfalls, a subject which is of some interest in this country. He dismisses accumulators as out of the question, and merely mentions the Geneva plan of using low-pressure turbines to pump water, during the twenty-four hours, into a high-pressure reservoir. M. Chédeville's specific is the erection of dams, which he thinks is much more generally possible than is usually imagined. The article concludes with an instructive concrete example. The stream to be utilised is a tributary of the Marne, and the village to be lighted is about half-a-mile away from a 33ft. fall. Careful measurements of the flow, extending over a twelvemonth, and including two periods of exceptional drought, show that the average flow is 49½ gallons per second, the maximum being 286 and the minimum 7¾ gallons per second. During the winter, a minimum of 17½ gallons per second may be counted on, which, allowing for turbine, dynamo, line, and other losses, would leave only some 5¾ H.P. available, or just about enough power to light 150 8-c.p. lamps. The stream happens, however, to run through a narrow valley with steep sides, and containing nothing but barren land, and by running a dam about 60 yards long across the outlet, a natural reservoir, having a capacity of 396 million gallons could be obtained, with a fall, when the reservoir was full, of about 70ft. This would enable the average winter flow of 66 gallons to be made use of, for the six hours of lighting only, at the rate of 264 gallons per second, which, with an average head of 53ft., and allowing for the usual losses, would leave 156 H.P. available, and enable several thousand 8-c.p. lamps to be alight simultaneously.

Telephone Disturbances at Marseilles.—Some unpleasant disturbance of the telephone circuits formerly took place in the neighbourhood of the electric tramway at Marseilles. Weird noises, from a low rumble to a piercing shriek, resembling, it is said, a syren (not the luring syren of Scylla, but the fog-horn of that name), were constantly heard in the telephones, and human speech had little chance of transmission. The civil authorities, interposing in the interest of the telephone, stopped the running of the electric cars. But this solution of the difficulty, savouring, as it did, more of autocratic power than of sweet reasonableness, could only serve as a temporary measure. Now, both the telephone circuits and the traction lines were, at that time, working on the single-wire system. The traction current was carried along the rails and returned by the overhead trolly wire. Leakage to earth occurred, of course, pretty freely. The telephones were worked on the earth-return system, with a single line connecting each instrument to the central office. Disturbances were the natural result of the proximity of two such systems. Ultimately the difficulties were overcome in what would appear to be the most reasonable manner, for the telephone proprietors were ordered to remove those portions of their lines which were immediately under the disturbing influence, and to replace these by poles capable of carrying wires at a sufficient height to be free from induction, the wires being duplicated so as to form a completely insulated metallic circuit for the telephone current wherever any such disturbance might be feared. Since the telephone lines have been doubled the disturbances arising from the proximity of the tramway system have been found to be negligible and incapable of interfering with the transmission of speech. While commenting on the effect of the Marseilles traction system, we may refer to the somewhat remarkable, and probably unique, system of earthing the positive pole and taking the current back through the trolly wire. This is a reversal of the usual practice, but it would, of course, make no difference to the disturbances caused by earth currents. The purpose in view in adopting this arrangement is the prevention of electrolytic action causing an increase in the line resistance.

ELECTROMAGNETIC THEORY.—LII.

BY OLIVER HEAVISIDE.

(Continued from page 145.)

§ 204. By replacing fictitious magnetic conductance of the medium outside the pair of leads by real electric resistance of the leads themselves, we have obtained the same results as regards the propagation of waves, subject to certain reservations referring to the practical applicability of the theory. It is worth while noticing, in passing, a certain peculiarity showing roughly when we may expect the theory to be admissible, and when it should fail. We know that in the transmission of waves along perfectly conductive leads the waves are continuously distorted if the medium be electrically conductive. Also, that by introducing magnetic conductivity into the medium we may reduce this distortion, and ultimately abolish it when the magnetic conductivity reaches a certain value. Now observe here that the correcting influence of the magnetic conductivity is exerted precisely where it is required, namely, in the body of the wave itself. The wave is acted upon in every part by two counteracting distorting influences, so that the correction is performed exactly; in other words, we obtain an exact theory of distortionless transmission.

But, on the other hand, when we employ the resistance of the leads to perform the same functions, the correcting influence is not exerted uniformly throughout the body of the wave, but outside the wave altogether; at its lateral boundaries, in fact. Nevertheless, for reasons before stated, we still treat the waves as if they preserved their planarity under the influence of the resisting leads. Whilst, therefore, we fully recognise and employ the finite speed of propagation of disturbances axially, or parallel to the leads, we virtually assume that the correcting influence of the leads is transmitted laterally outwards instantaneously. We may, therefore, perceive that the wave-length is a matter of importance in determining the applicability of the practical theory. It is of no moment whatever in the exact theory employing magnetic conductance; but, when we remove this property from the medium generally, and (virtually) concentrate it at the leads, we should at the same time keep the wave-length a considerable multiple of the distance between the leads if the practical theory is to be applicable. To see this, it is sufficient to imagine the case of waves whose length is only a small fraction of the distance between the leads, when it is clear that their correcting influence could no longer be assumed to be exerted laterally and instantaneously, as if the small portion of the leads between two close reference planes belonged to and was associated solely with the slice of the medium between the same planes.

We have referred in the above to the action of the resistance of the leads as a correcting one, neutralising the distortion due to another cause. But the same reasoning is applicable when the action is not of this nature. Thus, when the external medium is non-conductive, and the leads are non-resistive, we have perfect transmission. Making the leads resistive therefore now brings on distortion. We may now say that in order that this distortion should occur in the same way as under the influence of magnetic conductivity in the external medium, the wave-length should not be too small, as specified above. The practical theory is therefore the theory of long waves, and in the interpretation of the word "long," some judgment may be exercised as regards the leads and other matters, because there is no hard and fast distinction, and what may be a long wave under some circumstances may be a short one under others.

To illustrate this point, imagine that we have got an ingenious instrument (not yet made), for continuously recording the electromagnetic state of a non-conducting medium, say the air at a certain place (just as we have thermometric and barometric recorders), and that this instrument is so immensely quick in its action as to take cognisance of changes happening in very short intervals of time, say one thousand-millionth of a second. Now in applying this instrument to register the state of air traversed by electromagnetic waves, it is clear that the size of the waves must be considered in relation to the size of the instrument. If the instrument were one decimetre across, then waves of one kilometre in length could as well be regarded as of infinite length. But if only one metre in length, though it could still be used, there would be no longer the same accuracy of application. And if of only a centimetre in length, then it is plain that several waves would be acting at once on the apparatus in different parts, and the resultant effect recorded would not represent the history of the waves by any means.

Now as regards waves sent along parallel leads, it is obvious that light waves are totally out of the question, being immensely too short. On the other hand, telephonic waves are to be treated as long waves—very long, in fact—though they are short compared with telegraphic waves. But it is somewhat curious that the electromagnetic waves investigated by Hertz are sometimes so short as to come within the scope of the above reservational remarks, or of others of a similar nature. Whether the generation of waves by an oscillator be considered, or their effect on a resonator, or their transmission along leads, their shortness in relation to the apparatus employed may sometimes vitiate the results of approximate theories, and render caution necessary. For example, the plane-wave theory indicates that the attenuation factor for waves running along parallel leads is $\epsilon^{-Rx/2Lv}$ in the distance x, or $\epsilon^{-Rt/2L}$ in the equivalent time of transit t. This is when R and L are constants. If not, and the waves be simply periodic, then we may use the same formula with the effective values of R and L at the frequency concerned. But if this be true for long waves, we cannot expect it to continue true on shortening the waves to the transverse distance of the leads, more especially if we are ignorant of the precise type of the waves. At the best, we should not expect more than results of a similar kind. But not much has been done yet in the quantitative examination of Hertzian waves, for sufficiently obvious reasons.

In one respect, however, a formerly very strange anomaly has been cleared up satisfactorily. When Hertz opened people's eyes and made them see the reality of Maxwell's ether as a medium propagating electromagnetic disturbances at the speed of light, by showing their transmission across a room and reflection at a wall, the full acceptation of Maxwell's theory was considerably hindered for a time by his finding that the speed of waves sent along wires was much less than that of free waves. The discrepancy was a large one, and gave support apparently to the old view regarding the function of wires, which made the wires the primary seat of transmission, and effects outside secondary, due to the wires. And it came to pass that people, whilst admitting the truth of Maxwell's theory, yet made a distinction between waves in free space and "in wires." This was thoroughly out of harmony with Maxwell's theory, which makes out that the wires, though of great importance as guides, are nevertheless only secondary. On the other hand, it should be mentioned that Lodge found no such large departure from the speed of light in his experiments. But the matter has been explained by the discovery that an erroneous estimate was made of the permittance of the oscillator in the experiments, which apparently showed that the speed was largely reduced. When corrected, there is not left any notable difference between the speed of a free wave and of one guided by wires. Of course, there is no reason why reference to waves "in wires" should not be dropped, unless the laterally-propagated cylindrical wires are meant. These are secondary, and have no essential connection with the propagation of the primary waves through the external dielectric, although modifying their nature.

§ 205. When waves are left to themselves in ether without the presence of conductors, they expand and dissipate themselves. Even if they are initially so constituted as to converge to centres or axes, they will subsequently expand and dissipate. To prevent this we require conducting guides or leads. Now this usually involves dissipation in the leads; but the point at present under notice is the property of guidance only. We can stop the expansion in a great measure, and cause a wave to travel along wherever we wish it to go. Practically there are two leads, as a pair of parallel wires; or if but one wire be used, there is the earth, or something equivalent, to make another. But it is still much the same, as regards guidance,

Digitized by Google

when there is but one wire, if we choose to imagine the case of a single infinitely-long straight wire alone by itself in ether. If we make it the core of a plane electromagnetic sheet, this sheet will run along the wire just as well and in the same way as if there were a second guide. But the energy of such a sheet, even though of finite depth, and containing electric and magnetic forces of finite intensity, would be infinite. The quantity L, the inductance per unit length of guide, is infinite under the circumstances. We could not, therefore, set up such a wave from a finite local source. If we cause an impressed voltage to act axially for a very short interval of time across any section of the guide, say in a reference plane, the result is an approximately spherical wave. (To be perfectly spherical, the wire should be infinitely fine. The case is then that of a spherical wave-sheet with conical boundaries, already referred to, with the angle of the cone made infinitely small.) Its centre is at the origin of the wave, and as it expands, the portions of the wave-sheet nearest the wire become approximately parallel plane waves, one going to the right, the other to the left along the wire. But not being pure plane waves they are weakened as they progress, by the continuous expansion of the spherical wave of which they form a part. Nevertheless, we have the propagation of nearly plane waves of finite energy, or of a perfectly plane wave-sheet of infinite energy, along a single guide.

Now, this takes place outside the conducting guide, and the question presents itself whether we cannot transmit an electromagnetic wave along the interior of a tube, in a manner resembling a beam of light? We can certainly do so if we have a second guide within the first tubular one, for this does not differ substantially from the case of two parallel wires, each outside the other. But it does not seem possible to do without the inner conductor, for when it is taken away we have nothing left upon which the tubes of displacement can terminate internally, and along which they can run. A theoretical expedient is to carry the electrification forward at the proper speed. But we want the process to be automatic, so to speak, hence convection will not do. Again, if we make the displacement start from one portion of an electrically conducting tube and terminate upon the rest, we must insulate the two portions from one another, and then there will be a division of the charges between the interior and exterior, so that the result will be an external as well as an internal wave, or rather, one wave occupying both regions.

It would appear that the only way of completely solving the problem of the automatic transmission of plane waves within a single tube is a theoretical one, employing magnetic as well as electric conductance. To see this, imagine any kind of purely plane wave being transmitted in the normal manner through the ether, and fix attention upon a tube of the flux of energy, or a beam, using optical language. This beam cuts perpendicularly through the reference planes, in which the lines of electric and magnetic force lie, which again cross one another perpendicularly. The shape of the section of the beam by a reference plane may be arbitrary. But let it be quadrilateral, and so that it is bounded by magnetic lines on two opposite sides, and by electric lines on the other two. Now let the two sides of the tube upon which the displacement terminates perpendicularly, be electrically conducting thin sheets, and the other two sides, upon which the induction terminates perpendicularly, be magnetically conducting sheets. If the conduction be perfect, we shall not interfere with the transmission of the beam within the tube. That is, we have solved the problem stated. We may also notice that the external portion of the wave is not interfered with by the tube. But the interposition of the tube in the manner described renders the external and internal waves quite independent of one another, and either of them may be suppressed.

Similarly, if the interior region be made finitely conductive, electrically or magnetically, or both together, we can still investigate the transmission of waves along it in the same way as previously described for complete plane waves in a homogeneous medium made conductive, and the same applies to the external region, independently of the internal. Going further, we may do away with the diffused conductance, and concentrate equivalent resistances in the plates bounding the tubes, in the same way as we replace magnetic conductance of the external medium by equivalent electric resistance of the wires in passing from the exact plane-wave theory to the practical theory of wires in terms of V and C. That is, the two plates on which the displacement ends may be made electrically resistive, the resistance taking the place of the magnetic conductance in the interior; whilst the other two plates should be made magnetically resistive, if the interior electric conductance is also to be abolished. We may then express the propagation of waves in the tube in a manner resembling the practical theory of wires, though it will no longer be an exact theory. Nor will the interior and exterior regions be quite independent of one another now that the tube is only finitely conductive.

§ 206. Leaving these somewhat abstruse considerations, return to the practical theory concerning wires and its connection with the exact theory involving magnetic conductance. In the working out of the practical theory (which is not yet, however, the theory of official representatives of practice, though they are decidedly getting on) we have often to consider the effects due to intermediate insertions of resistance in the circuit of the leads, or of shunts across them, and other modifications. The question now is, what do these insertions represent in the exact theory?

Consider first a pair of parallel leads of no resistance. This will admit of the application of the exact theory, provided there be either no leakage or the external medium be uniformly conductive electrically. Now we know that when the leads have resistance, we make the transformation to the exact theory by substituting uniform magnetic conductivity of the external medium of the proper amount. Plainly, then, if we insert an electrical resistance in a lump in the circuit of the leads at any place, we should, in the exact theory, transfer it equivalently (changed to magnetic conductance) to the whole of the corresponding reference plane. That is to say, we must make the reference plane (outside the leads) uniformly conductive magnetically, so that the total magnetic conductance of the equivalent plate inserted equals the electric resistance which it replaces. We may then investigate the action of the plate on the waves traversing it in the manner described in a previous paragraph.

Similarly, the effect of an electrically conducting bridge across the circuit is equivalent to that of an electrically conducting plate at the reference plane. Their conductances are here not only equal, but of the same kind. We merely rearrange the leakage conductance so that it shall act uniformly, to suit plane waves.

Thus, a terminal short-circuit should be replaced by a terminal perfectly conductive plate, reflecting **H** positively and **E** negatively, or with reversal of sign; or, which is the same, C positively and V negatively. This maintains **E** and V permanently zero at the short-circuit, unless there be impressed force there. And a terminal disconnection may be represented, in the exact theory, by a terminal perfectly magnetically conductive plate, reflecting **E** positively and **H** negatively, or V positively and C negatively, thus maintaining C permanently zero at the disconnection.

A somewhat different kind of transformation is required in connection with impressed forces. Suppose, for instance, we insert an impressed voltage in the circuit of the leads at a given reference plane. How is it to be equivalently transferred to the whole plane, or to that part of it outside the leads, so that it may generate plane waves of the precise type belonging to the given leads? This is by no means so easy to follow up as the previous plate substitutions; but the following may sufficiently describe the essence of the transformation. First, when the generation of disturbances is concerned, it is not impressed electric force **e**, but its curl, that is effective. We must therefore find the curl of the given impressed force. If the latter is half in each wire, acting opposite ways, and uniform across their sections by the reference plane, then the curl of **e**, say **f**, is situated on the boundaries of the wires, and encloses them. Having ascertained the integral amount of **f**, it must be transferred to the whole reference plane outside the wires. Then the question arises how to distribute it properly. To answer this, it may be mentioned that when a distribution of

Digitized by Google

f starts into action, the first effect is to generate induction following the lines of f. This will be made clear later. If, therefore, we distribute the lines of f over the reference plane in such a way as to exactly copy the natural distribution of the magnetic lines in plane waves having the given leads for cores, we shall obtain what we want, viz., the sources so distributed as to generate plane waves of the required type on the spot.

By means of the above and similar devices, most telephonic and telegraphic problems may be converted to problems in an exact plane-wave theory. But we must always be careful to distinguish between a theory and the application thereof. The advantage of a precise theory is its definiteness. If it be dynamically sound, we may elaborate it as far as we please, and be always in contact with a possible state of things. But in making applications it is another matter. It requires the exercise of judgment and knowledge of things as they are, to be able to decide whether this or that influence is negligible or paramount.

(To be continued.)

THE HOLDEN-D'ARSONVAL UNIVERSAL REFLECTING GALVANOMETER.

The ordinary D'Arsonval reflecting galvanometer, which consists of a suspended coil placed in a strong magnetic field, is too well known to our readers to need description here. This instrument has received several important modifications at the hands of Major Holden; and the new instruments, which are manufactured by Mr. J. Pitkin, are now being put on the market by Messrs. Drake and Gorham, who are also the agents for other measuring instruments invented by Major Holden (see *The Electrician*, Vol. XXIX., p. 589). One of the most

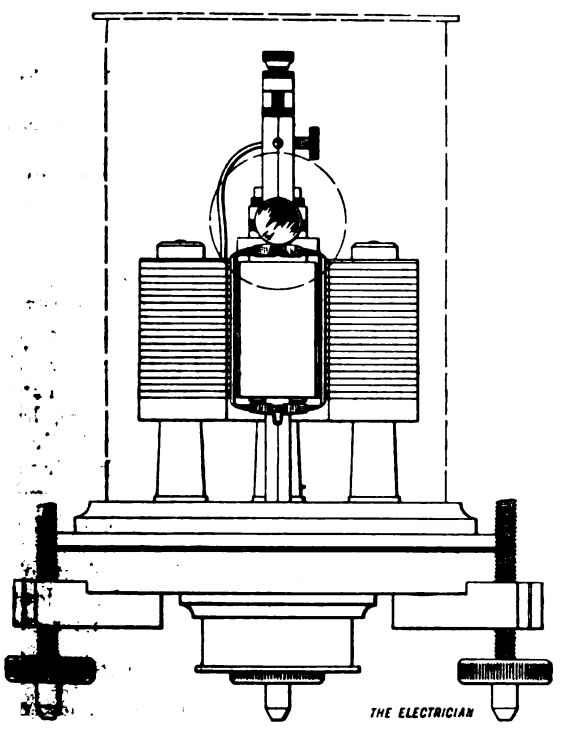

FIG. 1.—Holden-D Arsonval Galvanometer. Elevation

useful alterations and improvements is the arrangement which is made for quickly and expeditiously removing the suspended coil and its setting, and replacing it by another coil of different resistance, or by the hot-twisted-wire apparatus for alternating currents. The complete instrument is provided with a number of these interchangeable fittings, and the change from one to any of the others can be made without altering the adjustment as a whole on the testing table. The general form is shown in elevation in Fig. 1, and in plan in Fig. 2, and both these diagrams show one of the ordinary rectangular coils suspended in the field of the circular steel magnets.

The coil and frame is shown in Fig. 3. The coil is suspended on a fine strip made of flattened phosphor bronze wire. It is wound upon a light metal former; this former consisting, as it does, of a closed metal current, quickly damps the oscillations when it is placed in the magnetic field. The frame is provided

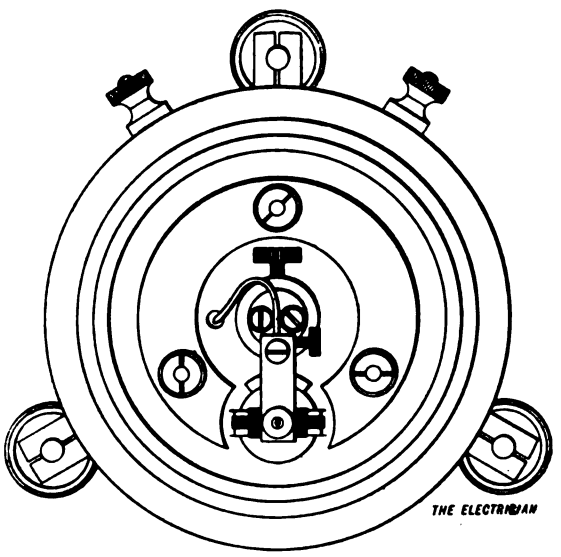

FIG. 2.—Holden-D'Arsonval Galvanometer. Plan.

with a tension screw at the top and a torsion head below. This torsion head can be got at by removing the lower cap without disturbing the cover of the instrument, thus enabling the spot of light to be brought approximately to zero. A cylindrical iron core is carried on the frame and is embraced by the coil. This core is screwed to a brass plug, which slides into a hollow cylinder fixed centrally into the instrument. The upper part

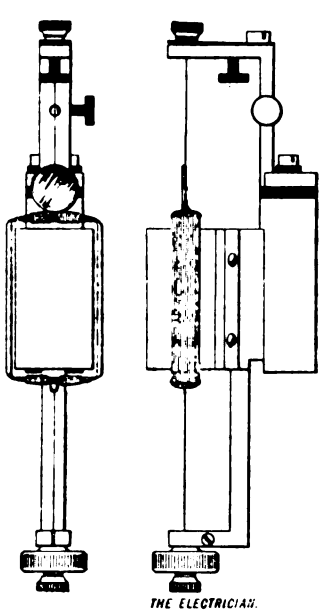

FIG. 3.
Coil and Frame.

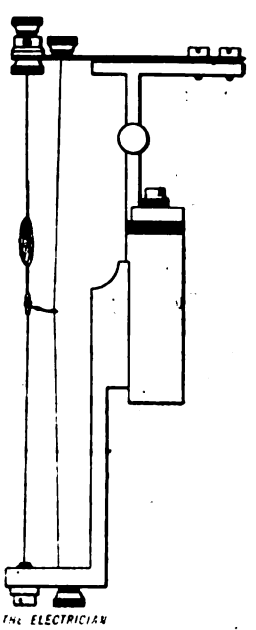

FIG. 4.
Hot Wire Frame for Alternating Currents.

of the frame is carried off this plug, and is insulated from it. A flexible wire connects this upper part with one of the terminals, the circuit being completed through the socket and the pillars. Each frame is thus held in a definite position, and, being provided with its own core, the constant of each frame and coil remains unaltered.

Not content with adapting this form of galvanometer for all purposes of continuous-current measurement, Major Holden has devised two methods of using it with alternating currents.

Digitized by Google

The rectangular coil is replaced by a vertical fine wire of platinum-iridium, through which the current is passed. This is shown in Fig. 4. In this latter adaptation the magnetic field is, of course, not utilised; but the device is carried on a plug which fits into the socket which holds the other frames. These are measured by means of the expansion of a thin wire, which acts upon a mirror so as to give it a turning movement. Between the two ends of the frame are fastened two wires having the same coefficient of expansion. These wires are insulated from each, and the current only passes through one of them. They are both kept tight by a spring which is adjustable and to which they are both connected.

The front wire carries in the centre of its length a small spindle to which is attached a silvered glass mirror. Around this spindle beneath the mirror is wrapped a very fine silk thread, the other end of which is connected to the back wire which carries the current. A torsion head attached to the front wires enables this to be turned so as to put a strain on the silk and deflects the back wire slightly from its position. When the current passes, the back wire is heated and lengthens; this allows the mirror to turn under the influence of the torsion given to its suspension wire. Major Holden has devised an ingenious modification of the rectangular coil fitting, by means of which an alternate current is measured by a magnetic torque. In this the rectangular coil consists only of one turn, which completes a local circuit with a small thermopile, the entire circuit being mounted on the suspending wires. The thermopile is warmed, and sets up a local current in the rectangular coil by virtue of the passage of the alternating current through a resistance *in the immediate neighbourhood of*, but not connected to, the thermopile. The strength of the local current, and the amount of deflection it will produce, will vary with the strength of the alternating current to be measured.

Besides the obvious convenience which the instrument offers on account of the variety of auxiliary fittings with which it is provided, there are numerous other advantages. The magnetic field in the air spaces into which the rectangular coil is placed is designed with special regard to uniform intensity; so that the readings on the scale are as nearly as possible proportional to the current passing through the coil. Portability is given to the instrument by providing it with a device for clamping the coil; and dead-beatness, by winding the coil on a metal frame, the eddy currents generated in which by the strong magnetic field will rapidly damp out oscillations. The instrument in its standard form is more compact than, and, it is claimed, more sensitive than the older patterns of this type of galvanometer. The standard pattern is provided with four interchangeable coils and frames, namely:—(1) A coil of 500 turns, with a resistance of 600 ohms; (2) a coil of 250 turns and 265 ohms; (3) a coil of 125 turns and 133 ohms; (4) a coil of 250 turns and 70 ohms resistance. Besides these, there are a number of frames for special purposes, some of which we have already described. The 500-turn coil with 10 megohms added gives a deflection of 1 millimetre at 2 metres with 1 volt.

A CONTRIBUTION TO THE THEORY OF ALTERNATE-CURRENT ELECTROLYSIS.*

BY DR. RICCARDO MALAGOLI.

For the history of the subject, and for the criticism I made on the theory given by Mengarini in 1891,† I refer the reader to a recent article of mine‡. It follows from what I have there said that only the fundamental principle of this theory, originated for the first time by Mengarini, can be retained; that is to say, we can only assume that the electrolytic phenomena produced by alternate currents may be considered as an integration of the ordinary electrolytic effects occurring during each alternation of the current. It is, therefore, necessary to investigate the elementary electrolytic phenomena which exhibit themselves at every alternation by applying to a single alternation the well-known laws of ordinary electrolysis, and then to integrate with reference to the number of alternations the current makes in any given period.

Assume that we are sending an alternate current through a voltameter having equal electrodes, which are not attacked either by the electrolyte or by its decomposed elements. Since there is no formula expressing the value of the electromotive force of polarisation of a voltameter, even when it has attained its maximum, it is impossible to apply mathematics to the determination of the shape of the electromotive force of polarisation of the voltameter. The method I used to effect this determination was necessarily a minute study of several particular cases.

If 2 T be the period of the alternate current, then $\int_0^T I\,dt$ is the quantity $s\,q$ (where s is the active surface of each electrode) of electricity, which passes through the voltameter at each half period. Since, for the same voltameter and electrolyte, the electromotive force of polarisation is only a function of q, our investigations must be directed to this element.

If q_0 be the quantity of electricity which has to traverse each square millimetre of surface on each electrode in order that the voltameter may attain its maximum polarisation, and if r be the interval of time at the end of which the current I (when flowing in a given direction) succeeds in producing this maximum, the different cases which may arise are—

$$q < q_0 \qquad r > T$$

$$q_0 < q < 2\,q_0 \qquad \frac{T}{2} < r < T$$

$$q = 2\,q_0 \qquad r = \frac{T}{2}$$

$$q > 2\,q_0 \qquad r < \frac{T}{2}.$$

In the first three cases there is no electrolytic decomposition. The voltameter, however, has not a variable polarisation, and if we take into account the shape of the stable polarisation curve it will be seen that at the end of each phase of the current we get equal and opposite polarities, zero being at the instant $\frac{T}{2}$, so that the first half of $s\,q$ is employed in depolarising the voltameter, and the second is occupied in polarising the reverse way. Only when $q = 2\,q_0$ are the initial and final polarisations equal to the maximum. When there is no electrolysis the curve of polarisation has a lag of a quarter-period with reference to the current.

If $q > 2\,q_0$, $s\,q_0 = \int_0^r I\,dt$, and in the interval from 0 to r the voltameter will be depolarised, and if $2\,sq_0 = \int_0^{r'} I\,dt$, the voltameter in the interval r to r' will acquire a polarity of opposite sign to that of the initial polarisation, and in the interval r' to T of the elementary phase, electrolytic decomposition will be possible. The curve of polarisation will, therefore, be at a maximum at the commencement of each phase, and will assume a maximum of opposite sign after the time r', keeping at this maximum until the moment T. This curve, therefore, has a lag of r with regard to the current curve, and this lag will be smaller, the larger q.

To find the law of the phenomenon, it is sufficient to determine theoretically the amount of electrolytic products developed by electrolysis in any given interval of time, let us assume an ideal case, $I = A \sin \frac{\pi t}{T}$, and if the stable state of polarisation has already been reached, the moment r' of the elementary phase at the end of which electrolysis will begin is given by the expression,

$$2\,s\,q_0 = A \int_0^{r'} \sin \frac{\pi t}{T}\,dt,$$

or,

$$r' = \frac{T}{\pi} \operatorname{arc\,cos} \left(1 - \frac{2\,s\,\pi\,q_0}{A\,T}\right).$$

On the other hand, the quantity of electricity, to which the electrolytic decomposition produced during the elementary phase is proportional, is

$$Q_0 = \int_{r'}^{T} I\,dt = A \int_{r'}^{T} \sin \frac{\pi t}{T} dt = \frac{2\,A\,T}{\pi} \left(1 - \frac{s\,\pi\,q_0}{A\,T}\right).$$

* Abstract (by the Author) of a Paper read before the Accademia Gioenia di Catania.

Digitized by Google

Taking $\frac{1}{T} = n$, the quantity of electricity which will pass through the voltameter during unit time of maximum polarisation, giving rise to electrolytic decomposition, will be

$$\frac{2A}{\pi}\left(1 - \frac{\pi s q_0 n}{A}\right).$$

Finally, if the phenomenon lasts (v) seconds, and if k is the electro-chemical equivalent, the liberated products in the voltameter will be represented by

$$Q = \frac{2A(v)k}{\pi}\left(1 - \frac{\pi s q_0 n}{A}\right).$$

Let me now explain the results contained in the preceding formula, results, which, as I have shown in the article referred to, are general. Assume that the current traversing the voltameter is supplied from a transformer feed by an alternator, so that we may assume that the number of alternations and current maxima are independent variables. Taking $A/S = \delta$ and observing that a negative value of Q has no meaning, we may arrive at the following conclusions from the above formula.

1. For every value of n there is a maximum current density δ, which is determined by the expression $1 - \frac{\pi q_0 n}{\delta} = 0$, at and below which electrolysis is impossible.

2. For every value δ' of the maximum current density above the preceding lower limit corresponding to a certain value of n, the phenomenon of electrolysis occurs even at a higher frequency, but there is a maximum limit n_0, determined by the expression $1 - \frac{\pi q_0 n_0}{\delta'} = 0$, after which electrolysis ceases and remains impossible for all values above n_0.

3. These limits depend upon q_0 and differ for different electrolytes.

4. Since the nature of the electrodes has no influence whatever on the value of the electromotive force of polarisation of the voltameter, provided they are not attacked either by the electrolyte or by its constituents, it may be inferred that the limits in question are also independent of the nature of the electrodes.

5. If the surface of the two electrodes is varied as well as the frequency, so that the product $s\,n$ remains constant, the electrolytic products obtained will also remain constant.

6. If only the current maxima are varied the resulting variations are not proportional.

7. If the current maxima and the surface of the electrodes, or the frequency, are varied in proportion, the corresponding variations of the amount of the electrolytic products are not (in the general case) rigorously proportional.

8. If only the electrode surface, or the frequency, is varied, the products obtained vary in opposite directions.

9. If the current is "redressed," the stable polarisation is (as in the case of a continuous current) represented by a straight line parallel to the axis of time, and in this case the products obtained are proportional to the total quantity of electricity traversing the voltameter; that which is used in polarising the voltameter being negligible. It follows from this that the amount of decomposed electrolyte is larger than it is in the case of an alternate current.

10. If on the same circuit several similar voltameters are arranged, containing unattackable electrodes and different electrolytes, the quantiy of electrolytic product obtained in each voltameter does not follow the laws of Faraday for ordinary electrolysis, since the energy spent in the polarisation and depolarisation of the voltameters is different.

All the experimental laws laid down by Mengarini are included in the above, excepting always that relating to the nature of the electrodes, which is not, moreover, of essential importance.

The formula $Q = \frac{2A(v)k}{\pi}\left(1 - \frac{\pi s q_0 n}{A}\right)$ which expresses the amount of electrolytic product liberated during the time (v) by the action of the current $I = A \sin \frac{\pi t}{T}$, may be considered as the pure and simple interpretation of experimental results obtained, and I may put forward a simpler form. The quantity of electricity which traverses the voltameter during a single phase of the current is given by the expression,

$$Q_e = \int_0^T I\,dt = \frac{2AT}{\pi} = \frac{2A}{n\pi}.$$

Substituting in the expression for Q, we have

$$Q = (v)\,n\,k\,(Q_e - 2\,s\,q_0),$$

and as $s\,q_0$ represents the quantity of electricity which must pass through the voltameter to allow it to obtain maximum polarisation, if we denote this quantity $s\,q_0$ by Q_0 the formula becomes

$$Q = (v)\,n\,k\,(Q_e - 2\,Q_0),$$

where $(v)\,n$ represents the number of alternations comprised in the interval in question. This new form shows that:—*The necessary and sufficient condition of alternate-current electrolysis is that the quantity of electricity which passes through the voltameter during a single alternation should be greater than twice that which is necessary to give to the voltameter its maximum polarisation. Electrolytic production ceases the moment these two quantities are equal, and the amount of decomposed electrolyte is proportional to the difference of these two quantities.*

M. VIOLLE ON THE LIGHT OF THE ELECTRIC ARC.

At a recent meeting of the International Society of Electricians, on the 7th inst., M. Violle described the experiments which he had been making on the electric arc. This experimenter has found that the light intensity of the positive carbon remains sensibly constant when the power supplied is varied in the proportion of 1 to 60. He has employed two methods of measurement: that of the spectrophotometer, the accuracy of which is really much greater than is usually stated to be the case; and a second method due to Arago, employing interference fringes. M. Violle exhibited a number of photographs of arcs of different candle-power, in order to show the constancy of the intensity of the positive carbon. By measuring the opacity of the negative plates, these photographs could be used as a gauge of the intensity. M. Violle recalled that this phenomenon had already been investigated by Rosetti, as well as by Capt. Abney and Silvanus Thompson; and everyone had attributed it to vaporisation of the carbon. This opinion was perfectly justified, for the deposit on the negative carbon has the appearance of having been condensed from vapour, and M. Violle had actually been able to produce crystals on this part. A photograph of an arc produced between carbons of purified retort carbon was next shown, and this exhibited a very curious appearance. Despretz had also observed that the phenomenon was due to volatilisation, but that there was fusion or more or less softening of the carbon; he had also attributed the deposit of carbon, which is formed in the arc, to the condensation of vapour of carbon, but he was unable to elucidate the question because he used impure carbons. M. Blondel has recently recognised that impurities in the carbon have not, in practice, any sensible effect on the intensity, which remains constant with carbons of very different quality. The intensity of the arc, he thought, was therefore a constant, and it might be utilised as such. M. Violle stated, in conclusion, that the temperature of 3,500°C. which is given for the arc, ought to be considered as a provisional value, although the true temperature is probably but little different from this figure.

Electric Light at the Krupp Works.—The electric light plant at the Krupp works, in Essen, which was commenced in 1876, has recently received considerable extension. The generating station is situated near the centre of the works, and includes six dynamos and steam engines of an aggregate of 650 H.P. There are two separate systems of distribution; one at 100 volts, continuous-current, for the glow lamps in the offices and workshops; and the other at 700 volts, continuous-current, for the arc lighting circuits and, by means of continuous-current transformers, for the more remote glow lamps. The low-pressure circuit consists of 3,200 metres of underground cable, feeding 1,400 glow lamps. The high-pressure cables are conveyed from the central station to three distributing stations at a distance of 4,900 metres, whence they radiate to the numerous arc lamp circuits which are carried overhead. Each of the arc lamp circuits consists of 16 lamps in series, and supplies 10 amperes. There are 384 arc lamps on all the circuits

NOW READY.

Volume XXX. of "THE ELECTRICIAN," price 12/6; post free, 13/6 abroad carriage extra.

Cases for binding Volume XXX., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

THE REGULATION OF ELECTRO-TECHNICAL LITERATURE.

The art of destroying old books is one of the many pernicious growths of these later times, and one that has attained a remarkably high state of development—as any British Museum Reading-room attendant will tell. The time-honoured recipe of giving an old volume a thorough stretching, followed by a prolonged course of reading in front of a log-fire, is only practised in these days by tyros. On the other hand, the useful art of destroying new books is in a disgracefully rudimentary stage. The smart reviewer, indeed, does his duty manfully, but, notwithstanding his efforts, he remains, when viewed in his proper light as a book-slaying machine, a most inefficient piece of apparatus. A good modern dynamo will return 97 out of every 100 watts put into it, mechanically; would that a reviewer could smash, pulverise, and annihilate 97 out of every 100 volumes that come within his range. The tide of electro-technical literature is flowing strongly just at present, and flowing as it does, in the direction of profit, no one feels inclined to take it at the flood and try to stem it after the manner of King CANUTE. Those who take a pride in thoroughness lament the existence of this literary Niagara, and the reviewers pound away with the heavy artillery of oracular castigation and the light guns of sarcasm and irony. But to no purpose. The lamentations are unheard and the witticisms unheeded. Both the one and the other serve merely as a sort of cerebral safety-valve to the individual who indulges in them. As the papers related but a few days ago, a piece of slovenly riveting on the part of a workman went nigh to endangering a four-million-dollar man-of-war. We wish it were possible to calculate the damage done by bad workmanship on the part of those who render themselves

Digitized by Google

responsible for technical books. Putting aside blunders, how much valuable time is wasted owing to obscurities of style, and to the undue prominence given to theoretical or mathematical futilities ?—defects originating nine times out of ten in lack of knowledge, lack of literary skill, and slovenly workmanship. If we add to the time so wasted the time spent in unlearning and find the ratio which the sum of these two items bears to the waking working hours of the average man, surely retributive justice is painfully and inadequately represented by a smart review which advertises as much as it damns. The solemn and formal bastinado of the author, followed by an *auto-da-fé* of his works, would seem more commensurate with the offence.

The evil is, alas, of long standing. Twenty years ago the Comte DU MONCEL, his own literary perpetrations notwithstanding, prefaced the 3rd Edition of his three-volumed "Exposé des Applications de l'Électricité" with a lengthy diatribe. "These books," said DU MONCEL, referring to those of the popular science order, "have put really serious works out of countenance; works in which real science is more difficult to acquire, and the majority of publishers, naturally more concerned with their own interest than those of science, rarely undertake now-a-days the publication of truly scientific works. On the other hand, if the superficial knowledge required by the perusal of works, such as I am speaking of, has given rise to investigation and invention, how many illusions have they not also given rise to? . . . A number of these books, moreover, are written by people who are not specialists in the subjects with which they deal; who only know science at second-hand without the mathematical and theoretical knowledge necessary for a just appreciation of the facts; and who, not grasping principles, only attach importance to form, and to the effect produced upon the reader. A great personage whom it was proposed to transform from a man of letters into a statesman, remarked that a hare was a necessary antecedent to jugged hare. In the same way, some knowledge of science is of necessity antecedent to a scientific book, even of the popular order. . . . . But such is not the spirit which pervades popular science publications to which the Press daily gives birth. Sensational inventions and phenomena which appear most likely to dazzle the mind are picked out and described somewhat after the manner of conjurors, and the public, but slightly in touch with true science, believes that all has been said that can be said. For instance, many books specially devoted to electricity allot an undue proportion of their space to tricks and devices employed on the stage by conjurors to attract the public attention, whilst no mention is made of the admirable applications of electricity to apparatus of precision, to chronographs, meteorological apparatus, the art of engraving and similar industries. In the many curious phenomena of induced currents of high tension such writers only see the illumination of tubes more or less ingeniously arranged to produce the maximum luminous effect. What is still more strange is that the majority of the books in question are cast in the same mould. It would seem as if certain inventions, which have been the subject of more or less interested puffing, had been taken as their theme as well as certain ill-digested discoveries; whilst, in regard to the others, the word had been sent round to maintain a conspiracy of silence."

Let us, then, pending the slow evolution of an automatic extinguisher of flat, stale, and unprofitable scientific books, by the gradual education of the public taste, endeavour to improve upon the reviewer. We have already hinted at the introduction of foreign methods, and the same source is fruitful of similar expedients for training up public opinion in the way it should go. Electro-technical Institutes abound; cannot we institute an electro-technical version of the old Congregation of the Index, charged with the important function of sitting upon all names of printed puerilities of an electro-technical kind. Given sufficiently eminent specialists at sufficiently high salaries, acting as censors and licensors of electrical literature, we predict the sudden demise of 95 per cent. of existing books and rioting in Trafalgar-square by out-of-work reviewers. A perusal of MILTON'S "Areopagitica" might possibly give rise to misgivings in some minds as to the expediency of such an institution. "As good almost kill a man as kill a good book." Why, certainly; but what if a thousand bad books are destroyed at the same time? The censors might license none but their own books. Any censor directly or indirectly concerned in the writing of a book should be *ipso facto* disqualified. The standard might be raised too high. Possibly. But at first the datum line might be drawn at any text-book, hand-book, pocket-book, or similar publication that did not contain a minimum of one fresh idea and one new illustration. We make the suggestion for what it is worth, even though its figure of merit be only "one *ob.*" Provided the floodgates of literary futilities be kept shut, at least for a time, no one need inquire too closely as to the means.

THE INCANDESCENT LAMP: ITS MANUFACTURE AND USE.*

BY GILBERT S. RAM.

The light-emitting portion or burner—called by Edison the filament—of the incandescent lamp, it is well known, is composed of carbon, which is raised to a state of incandescence by the passage through it of a current of electricity. Carbon is not the only substance which can be used. The number of possible materials is, however, very small, and for two reasons. Firstly, because the material must be capable of withstanding a very high temperature; and secondly, because it must be a conductor of electricity. These two conditions exclude nearly everything except carbon and some of the metals. Of the metals which are sufficiently plentiful, platinum alone possesses the desired qualifications to a degree which renders its use possible. Platinum has a very high melting point, and will stand a very high temperature, but the temperature necessary for an economical incandescent lamp burner is far above that even of the melting point of that metal.

The incandescent electric lamp, though a great advance upon most other artificial sources of illumination, gives us at best only a very inefficient method of obtaining light. That is to say, the proportion of the luminous radiation to the total radiation is very small. When the temperature of a filament is raised by the expenditure in it of more and more energy it becomes increasingly efficient. The efficiency which can be attained is however, limited, by the temperature which the filament will stand. Carbon will stand a temperature higher than the melting point of platinum, and it, therefore, constitutes a more efficient burner.

Certain metallic oxides possess in a remarkable degree the power of resisting very high temperatures. It has, in consequence, been proposed to utilise these in some way, and mention of them has been made in some of the earliest patents for electric lamps. Here, however, the difficulty occurs that metallic oxides are non-conductors of electricity, and, consequently, cannot be used alone. They can only be used in conjunction with some conductor—either a metal or carbon. The author has tried coating both platinum and carbon with oxides such as alumina, magnesia, lime, &c., but has always met with the difficulty, in the first place, that the coefficient of expansion

* Abstract from a book to be published shortly by "*The Electrician*" Printing and Publishing Company (Limited). All rights of re-publication reserved.

Digitized by Google

of the oxide is different from that of the carbon or metal, and, consequently, the coating cracks and falls off.

It has been pointed out by Prof. S. P. Thompson that the temperature of the crater of the arc in an arc lamp is constant, and is the temperature of the volatilisation of carbon. Any other substance contained in the carbons volatilises instantly when reaching the arc. The carbon itself volatilises at that temperature, and all other substances appear to do the same either at that temperature or below. This being the case, it would appear futile to attempt to increase the durability of arc lamp carbons by the addition of any foreign substance.

It is possible, however, that some substance other than carbon may yet be used successfully as the light-emitter in an electric lamp. Even if all metallic oxides are dispersed at a temperature less than that of the arc when used in conjunction with carbon, they are not all necessarily volatilised at that temperature. The volatilisation may be simply a secondary effect, the oxide having been first reduced by the carbon. It does not appear to be impossible that some oxide or mineral substance may be found to be stable at temperatures higher even than that of the arc if there be no carbon present. The great trouble in using any such substance in the same manner as the filament of an ordinary incandescent lamp is that of electrical conductivity. It is possible that some of them might consent to conduct sufficiently if subjected to a very high E.M F., such as can be produced by transformers. We have seen during the past year slate pencils used in the place of carbons in the arc lamp, slate being considered an insulator at ordinary electrical pressures. Such an incandescent lamp, however, if ever constructed, would hardly be suitable for domestic use. Again, although mineral substances when mixed with carbon are all reduced or volatilised in the arc, such mixtures may, nevertheless, be used for incandescent lamp filaments at a temperature much below that of the arc.

Great improvements may yet, however, be looked for in the carbon itself. It is well known that carbon prepared by some processes will last much longer than that prepared by others. The efficiency of a carbon depends upon the temperature at which it can be run. The higher the temperature the greater the efficiency. The limit to the temperature possible is that of the volatilisation of carbon. This temperature in the case of an incandescent lamp is probably lower than that of the arc. The temperature of volatilisation of carbon in vacuo is likely to be much less than at atmospheric pressure. We can, therefore, never hope to get the carbon of an incandescent lamp anything like as bright as the crater of an arc lamp.

Long before the temperature of volatilisation of carbon in vacuo is attained, there is another effect to be considered which puts a far lower limit upon the temperature which can be maintained in practice. Apart from volatilisation properly so called, there is an action going on by which particles of carbon are dissociated from the filament and thrown off upon the glass globe (which is usually called the bulb) of the lamp. This action, unfortunately, begins at a comparatively very low temperature—a little above red heat—and increases very much at higher temperatures, so that, although the filament may be far below the temperature of volatilisation, yet it is fast falling to pieces, and the bulb is becoming greatly obscured by the black deposit of these particles of carbon. It is, then, in overcoming this lower limit to the temperature that improvements must first be made. Some carbons are much better than others in this respect. The best carbon is that which at the highest possible temperature disintegrates at the slowest rate.

Much has been said and written about the so-called efficiency of surface, or emissivity, of different varieties of carbon. Some varieties have a greater emissivity than others in the proportion of about 3 to 2. That is to say, when running at the same efficiency (watts per candle), two carbons of precisely the same dimensions may be giving different amounts of light by as much as the above ratio. Or two carbons, one having only two-thirds of the surface of the other, may, when at the same efficiency, be giving an equal amount of light. It has sometimes been supposed that the one with the smaller surface is, therefore, better than the other. The reverse, however, is usually the case. The filament with the smallest emissivity is generally the best. A high emissivity usually means a dead black surface, a low emissivity, a polished white one. The dull black surface is generally a softer carbon, and one which disintegrates more quickly than the other. The only advantage in the high emissivity is that the filament is, therefore, shorter and may be accommodated in a smaller bulb. The size of the bulb, however, should not be determined by the length of the filament so much as by the candle-power. A large candle-power lamp may have a short filament, but it should not for that reason be put into a small bulb. These matters will be further dealt with in a subsequent chapter.

The chief aim of the lamp-maker, next to that of producing a durable carbon, is to make filaments which will be all alike when finished. To be commercially successful a lamp-maker must be able to make his filaments within a very little all alike in every particular, that is in dimensions (length, circumference, cross-section), in quality of surface and in specific resistance. Many different methods of preparing carbon have been proposed. Whatever the method, there is one operation which almost all of them necessarily include—that of roasting or baking the material in a furnace out of contact with the atmosphere, in order to drive off, as far as possible, everything contained in the material which is not carbon. In most cases an entire change in the nature of the material is produced by the process. One of the first methods to be tried was that of forming the filament out of a paste made of ground carbon, with a binding agent such as a solution of sugar or caromel. Such a paste was squirted or moulded to the desired shape, dried, and then baked. This, of course, produced practically the same material as is used for the carbons of arc lamps. The difficulty in this method is to produce fine and uniform filaments. In any event, however, the resulting carbon is not compact enough for the purpose, and it rapidly disintegrates when used in a lamp. Edison proposed a mixture of lamp-black and tar, an utterly worthless process in itself, but one which has, nevertheless, become famous in the history of lamp making. Processes such as these involve the baking of the material in order to drive off the volatile matter contained in the binding agent.

The successful processes are not those by which the filaments are formed direct from a substance containing carbon as such, but from a material containing carbon in chemical combination, such as silk, hair, woody fibre, or pure cellulose. Such substances require baking at a high temperature in order to reduce them to carbon, their other constituents being driven off by the heat. The process of baking in this case is generally called carbonisation. The only processes which do not include that of baking or carbonisation are those by which the filaments are deposited or built up from the carbon contained in some vapour or liquid such as illuminating gas or petroleum oil.

(*To be continued.*)

ON THE MEASUREMENT OF INTERNAL RESISTANCE OF PRIMARY BATTERIES WHICH POLARISE.

BY E. C. RIMINGTON.

To obtain the internal resistance of a primary battery appears at first sight a very simple affair. If any text-book on electrical testing be consulted a great many different methods will be found, any one of which is supposed to be capable of giving the desired result. As long as the primary battery to be tested is of a kind very slightly subject to polarisation, such, for example, as a Daniel cell, this is probably true, and one method will give a value for the internal resistance differing but slightly from that obtained by another. If, however, the resistance of a battery subject to polarisation, such as a Leclanché or any of the dry forms of cells, be measured by two different methods, or even twice by the same method,

Digitized by Google

values which differ very considerably from each other will be obtained.

It is well known that all methods for measuring internal resistance consist in practically making two measurements, the battery giving a different current in each case. Now if there be any polarisation the electromotive force of the battery, instead of being constant, which it is supposed to be in getting out the result, will be a function of the current being less as the current is increased; this will, of course, produce an error which may be very considerable. One of the most usual methods of determining internal resistance is the following, or some slight modification of it.

The battery of internal resistance ρ, which is to be found, is circuited through a resistance R, and its terminal potential difference is measured, let the latter be V; the battery is then circuited through an external resistance r, and the terminal potential difference again measured; call it v.

Then
$$\frac{V}{v} = \frac{\frac{\rho + R}{\frac{r}{\rho + r}}}{} = \frac{R(\rho + r)}{r(\rho + R)},$$

or,
$$\rho = \frac{R r (V - v)}{R v - r V}.$$

As the potential differences occur as ratios it is unnecessary to know their value in volts, so that if the instrument used in measuring them give deflections proportional to the potential difference at its terminals, then if D and d are the respective deflections

$$\rho = \frac{R r (D - d)}{R d - r D} = \frac{r (D - d)}{d - \frac{r D}{R}}. \quad . \quad . \quad . \quad (1)$$

In practice R is generally infinite, or the deflection D is taken with the battery uncircuited; then

$$\rho = \frac{r (D - d)}{d}.$$

The deflections D and d can be obtained by connecting a high resistance proportional reading galvanometer across the battery terminals to act as a voltmeter, or by charging a condenser from the battery terminals and discharging it through a galvanometer: this latter is generally known as Kempe's method.

Major Holden's instrument for testing primary batteries, described in *The Electrician*, June 23rd, p. 200, works on this method; in it R = 8 ohms and r = 2 ohms. The resistance of the coil, which acts as a voltmeter, is not stated, but it is probably sufficiently high to make its joint resistance in parallel with the 8 ohms very little less than 8 ohms.

Let us consider the probable error produced in measuring the resistance of a cell or battery by this method, assuming that there is *no* polarisation.

From equation (1) $\rho = \frac{R r (D - d)}{R d - r D}$.

Assume an error x made in the value of d. Then the value of ρ (or ρ_1) becomes

$$\rho_1 = \frac{R r (D - d - x)}{R (d + x) - r D}.$$

The error in ρ is

$$\rho - \rho_1 = \frac{R r (D - d)}{R d - r D} - \frac{R r (D - d - x)}{R (d + x) - r D}$$

$$= \frac{R r (R - r) D x}{R d - r D) \{R (d + x) - r D\}}$$

$$= \frac{R r (R - r) D x}{R d - r D)^2} \text{ approximately.}$$

Hence the fractional error in the value of ρ;

or
$$f = \frac{\rho - \rho_1}{\rho} = \frac{(R - r) D x}{(D - d)(R d - r D)}. \quad . \quad . \quad . \quad (2)$$

If R = ∞ (2) becomes

(2a) $f = \frac{D x}{(D - d) d}$ and the value of d that makes f a minimum is obviously $d = \frac{D}{2}$, so that r should be approximately equal to ρ.

In Major Holden's instrument R = 8, r = 2.

Therefore
$$f = \frac{3 D x}{(D - d)(4 d - D)}.$$

In the illustration given of the instrument the scale reads to 0·1 of a volt, but from the column of figures of measurements made with the instrument it apparently reads to 0·01 of a volt. Let us suppose 0·01 as the probable error in taking a reading. Taking the third test given, viz., that of an E. C. C. dry cell, D = 1·43, d = 1·38, the probable value of f

$$= \frac{3 \times 1{\cdot}43 \times 0{\cdot}01}{(1{\cdot}43 - 1{\cdot}38)(5{\cdot}52 = 1{\cdot}43)} = 0{\cdot}21,$$

or 21 per cent. is the probable error in the value of ρ.

In the case of No. 4, a Leclanché-Barbier dry cell of considerably higher internal resistance than the E. C. C., D = 1·3, d = 1·05,

$$f = \frac{3 \times 1{\cdot}3 \times 0\ 01}{(1{\cdot}3 - 1{\cdot}05)(5{\cdot}2 - 1{\cdot}3)} = 0{\cdot}04, \text{ or 4 per cent. only.}$$

We must now consider the effect of polarisation. When the cell is circuited through the lower resistance, it gives a larger current, and has, consequently, a smaller electromotive force, its potential difference will therefore be less than it would have been if there had been no polarisation. In formula (1) the value of d will read too small, and as it can be readily seen this will make the observed value of ρ greater than its real value.

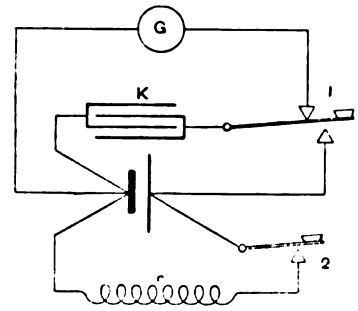

FIG. 1.

This error, due to polarisation, is a very serious one in cases of all cells such as Leclanché or dry cells, and may make the worked out value of the internal resistance more than double its real value. The author, some years ago, made a large number of experiments on determining the internal resistances of Leclanché cells by Kempe's method and various modifications of it to try and obtain the method that would give the value of ρ nearest its true value. He found that the best results were obtained by circuiting the battery through a resistance about four to six times it internal resistance until its terminal potential difference had attained a fairly constant value, then breaking the circuit and *instantly* measuring the potential difference in open circuit.

The best method of doing this is shown in Fig. 1. K is a condenser. Key (2) is clamped down, and the terminal potential difference observed at intervals by pressing key (1) so as to charge the condenser, then releasing it and allowing the condenser to discharge through the galvanometer G. When a constant throw d is obtained, key (1) should be depressed, key (2) released, and *immediately* afterwards key (1); the throw D obtained will be that due to the electromotive force of the battery when polarised, or its potential difference in open circuit. Then, of course,

$$\rho = \frac{r (D - d)}{d}.$$

Theoretically, the best value to give r is equal to ρ, so as to make $d = \frac{D}{2}$; but this value would make the battery polarise to excess, to say nothing of running it down, so that the value given for r, viz., four to six times ρ, or even greater, will be found to give better results; in fact, the larger r can be made

Digitized by Google

the better, provided the difference between D and d is sufficient to prevent a small error made in the reading of either producing too large a fractional error in the value of ρ. Now we know

$$\frac{d}{D} = \frac{r}{\rho + r},$$

and formula (2a)

$$f = \frac{D\,x}{(D-d)\,d}.$$

If $r = \rho$ $\quad d = \frac{D}{2}$ and $f = \frac{4x}{D}$

$r = 4\rho$ $\quad d = \frac{4}{5}D$ and $f = \frac{25\,x}{4\,D} = 6{\cdot}25\,\frac{x}{D}$,

$r = 6\rho$ $\quad d = \frac{6}{7}D$ and $f = 8{\cdot}1\,\frac{x}{D}$,

$r = 8\rho$ $\quad d = \frac{8}{9}D$ and $f = 10{\cdot}1\,\frac{x}{D}$.

It will be seen that making $r = 6\rho$ only makes the fractional error in ρ due to a given error of observation about double what it would be if $r = \rho$, but it will make the error due to polarisation very much less. Of course, the above remarks concerning the best value to make r apply to any of the methods of measuring internal resistance by observing the potential differences on open circuit, and with the cell circuited through r.

If it be desired to employ a galvanometer as a voltmeter instead of the galvanometer and condenser in the above method, the galvanometer should be as dead beat a one as possible, such as a d'Arsonval; even with this, however, it will not be

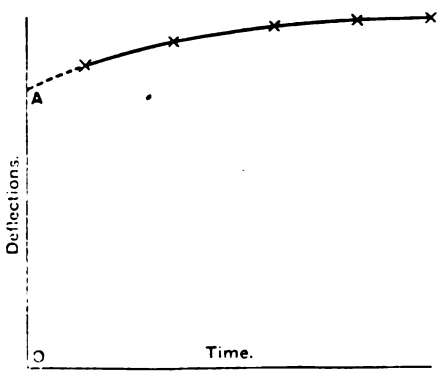

Fig. 2.

possible to obtain a reading at the instant of breaking the circuit through r, and the reading will be continually increasing, due to the cell recovering from polarisation. The following procedure may then be employed. Note the time at the instant of breaking the circuit r, then take time readings of the deflection, reckoned from the instant of breaking the circuit, and beginning as soon as the deflection is readable. On a piece of squared paper, plot times as abcissæ, and the readings as ordinates, this will give a curve somewhat similar to Fig. 2, where the crosses represent the readings. This curve can then be produced backwards by hand fairly accurately, as shown by the dotted line, and the reading at the instant after the circuit is broken, or D, will be approximately given by O A, the reading where the dotted curve cuts the vertical axis.

Of course this method has the disadvantage of running down the cell to be tested, as it is generally found necessary to keep it circuited for a good many minutes through r before it has polarised down to a fairly constant electromotive force, but it was found that much more consistent results could be obtained by this than by any other modification of the potential-difference method, and, moreover, ones that agreed much more closely with those given by more accurate methods of determining internal resistance as described below.

Any test for internal resistance founded on the determination of either the potential difference or the current when the battery is circuited through two different resistances can, however, never give really accurate results if there is much polarisation, since the most that can be done is to try and allow approximately for the effects of this polarisation, or obtain the reading very rapidly, as in the case of the condenser method, before polarisation or recovery from it have become appreciable, and this is very difficult to do effectually.

There are, however, methods by which polarisation can be absolutely eliminated; they possess the advantage, moreover, of being balance methods, and are, therefore, susceptible of greater accuracy than tests depending on the reading of deflections or throws, independently of their elimination of polarisation. One of these is a modification of the method of making Lord Kelvin's well-known test for internal resistance by turning it into a balance method, and invented by the author six or seven years ago, though it has not to his knowledge been hitherto published. Lord Kelvin's test consists in circuiting the battery to be tested in series with an adjustable resistance and a galvanometer, and noting the deflection, a shunt is then applied to the battery,

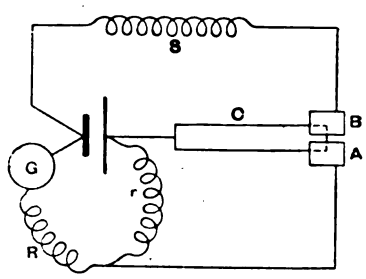

Fig. 3.

and the adjustable resistance reduced until the deflection is the same as before. Then if S is the resistance of the shunt, r the amount, by which the adjustable resistance has been reduced, $R + r$ its original value, and G the galvanometer resistance.

$$\rho = \frac{r\,S}{G + R}.$$

The test as it stands is practically useless if the battery to be tested polarise to even a slight extent, as the electromotive force when the shunt is on will be less than what it is with no shunt, while the formula is obtained on the supposition that the electromotive force is the same in the two cases. Suppose the above test to be connected up as shown in Fig. 3, using a key with a movable lever c, making contact *simultaneously* with the two contact pieces a and b when depressed; this has the effect of putting on the shunt and cutting out r at the same instant, so that if r be correctly adjusted, and there be no polarisation, the deflection on the galvanometer G would remain

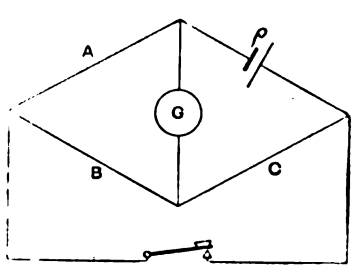

Fig. 4.

unchanged, and the test becomes a balance method instead of a reproduced deflection one. When r is too large, the deflection will increase on pressing the key, and when r is too small, decrease.

Suppose, now, that we are testing a cell which polarises; on pressing the key the cell gives more current, and its electromotive force falls off, so that, even if there were an exact balance supposing no polarisation, there will be a diminution in the deflection on account of this falling off in electromotive force. Any fall in the deflection on pressing the key must be then due to either or both of the two following causes: (1) r too small; (2) polarisation. The slightest movement of increase of deflection on pressing the key, even if immediately followed by a decrease, can only be due to r being too large.

Digitized by Google

egin, then, by adjusting r until, on pressing the key, a ement of increase is obtained; this movement will be iediately followed by one in the direction of decrease, and to polarisation. Then gradually reduce r, until, on press- the key, there is just no movement of increase, while, if r ery slightly increased, the movement of increase of deflec- is again visible. This value of r will be the one that must sed in the formula. In this manner the effect of polarisa- is completely eliminated, however badly the battery to be d falls off in electromotive force. Of course the galvano- r is used to a false zero, the index being brought on to the by means of a neutralising magnet, or another coil carry- a circuit.

he best conditions for this making test are to make r large, consequently S small; S should not, however, be made too ll, on account of running down the cell; the effect on the ıarisation does not, of course, matter; somewhere rather ıter than ρ is probably the best value for S, if allowable, of course, r must be less than $G+R+r$, and this latter uld be as small as will allow a convenient deflection to obtained, using a very large false zero.

The objection to this method of determining internal resist- e is the difficulty of making a key, in which the con- t of c with a and b takes place absolutely simultaneously; best form is probably a long plunger, fitting accurately in ylinder for the movable piece c. The author has, however, ained very fair results with a form made like an ordinary ng contact key, but with two contacts and contact pieces ead of the ordinary single one; great care had, however, to mployed in using it, as the slightest twist in pressing it ed one contact to be made slightly before the other.

robably the best and most accurate method of taking rnal resistance is Mance's Bridge method (as in Fig. 4), A B being the ratio arms of the bridge and C the adjustable a. C is adjusted until there is no alteration in the deflec- n whether the key be up or down, that is if there be no arisation then $\rho = \frac{A\,C}{B}$. If, however, the cell polarises, the ct of the polarisation must be eliminated by the method of cedure given in the last test, over which it possesses the vantage of requiring no special form of key but simply an linary make-and-break key.

STRUCTIONS FOR PREPARING CLARK STANDARD CELLS.*

BY DR. K. KAHLE.

The instructions here given for the preparation of Clark cells are npiled on the basis of the experience gained in the Reichsanstalt, d are intended to place a reliable cell within the reach both of estigators requiring a standard of E.M.F. for their work, and of rkshops supplying such cells for technical purposes.

Besides the form of element here recommended, which may be ced back to the **H** form proposed by Lord Rayleigh, there are ny others, such as that proposed by the English Board of Trade d by Dr. Feussner. The considerations which gave rise to the rm here described are mainly the following:—The cell was to be sily reproduced and at the same time portable, and its E.M.F. ıs to adjust itself rapidly to changes of temperature. That the w cell is in these points to be preferred to the older patterns ll be shown in detail in a communication shortly to be published a continuation of the Paper published by me in this journal, 92, p. 117, "Contributions to the Study of the E.M.F. of the rk Standard Cell." The instructions concerning the chemicals be used in the cell appiy everywhere, and do not differ mate- lly from those given in the third Board of Trade Memorandum the Preparation of the Clark Standard Cell.

Definition and Properties of the Cell.

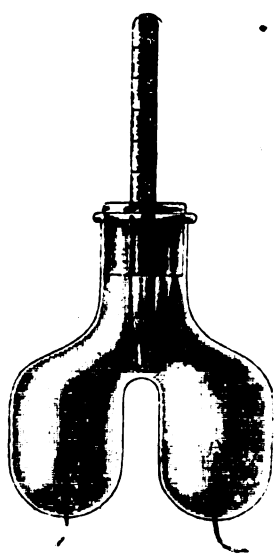
The cell contains mercury as the positive electrode, amalgamated nc as the negative electrode, and as electrolyte a concentrated lution of zinc sulphate and mercuric sulphate. Its E.M.F. amounts to 1·438 volt at 15deg.,* and decreases between 10deg. and 25deg. by 0·00115 volt with an increase of temperature of 1deg.

Construction of the Cell.

The vessel used for the cell consists, as shown in the figure, of two vertical branches closed at the bottom, and joined at the top into a neck closed by a ground-glass stopper. The diameter of the branches should be at least 2cm., and their length 3cm. The neck of the vessel should be 1·5cm. wide, and at least 2cm. long. Platinum wires about 0·4mm. thick are fused into the bottom of both branches.

The vessel is filled in a manner depending upon whether the cell is to be used at the place of construction or is to be transported.

In the former case pure mercury is poured into one branch, and into the other an amalgam of about 90 parts mercury and 10 parts zinc, which is fluid when hot and solidifies on cooling. The platinum wires must be completely covered by the mercury and the amalgam respectively. Upon the mercury is poured a layer of paste 1cm. deep, made by rubbing together mercuric sulphate, mercury, zinc, sulphate crystals, and concentrated solution of zinc sulphate. This paste and the amalgam are then both covered with a layer 1cm. deep of zinc sulphate crystals, and finally the whole vessel is filled with concentrated zinc sulphate solution until the stopper on being introduced just touches the surface. Care should however be taken that the vessel contains a small air-bubble, since that prevents its bursting in the case of a great rise of temperature. At the final closing of the vessel the glass stopper is brushed over at its upper edge with shellac dissolved in alcohol and then firmly inserted.



If the cell is to be sent away, a circular electrolytically-amalgamated piece of platinum foil, about 1cm. long and 0·1mm. thick, takes the place of the mercury, and is firmly attached to the platinum wire introduced through the bottom. Zinc amalgam forms, as before, the negative electrode, and is covered with a layer of zinc sulphate crystals 1cm. deep. The rest of the vessel is filled up to the stopper with mercuric sulphate paste. The final closing is effected as already described.

Preparation of the Materials to be Used in the Cell.

Mercury.—All mercury to be used in the cell should be purified by the ordinary processes, and distilled *in vacuo*.

Zinc.—The commercial pure zinc may be used straight away. To prepare the amalgam, add one part zinc to nine parts mercury, and keep both in a porcelain dish at 100deg., stirring gently until the zinc is completely dissolved in the mercury.

Sulphate.—Before use test the commercial zinc sulphate for acid with litmus and for iron with potassium sulpho-cyanide. If it is sufficiently pure it may be at once re-crystallised in the way detailed below. If it contains appreciable traces of free acid, equal parts of the zinc sulphate and distilled water are boiled with zinc filings in a suitably formed porcelain dish until no further gas is given off at the zinc, and the solution shows after cooling a white, or, in the presence of ferric hydrate, a brownish precipitate of zinc hydrate. If the solution was free from iron it may be filtered off after standing for two days. Otherwise it is again heated to 60 or 80, and

* Communicated to the *Zeitschrift für Instrumentenkunde* by the Physikalisch-Technische Reichsanstalt. In connection with the subject matter of this Paper, see also Dr. Lindeck, *Zeitschrift für Instrumentenkunde*, January, 1892; Rayleigh, *Phil. Trans.*, 175, p. 411, 1884, and 176, p. 781 1885; and J. Swinburne, *The Electrician*, September 4, 1891.—*Tr.*

* This number rests on the supposition that 1 ohm = 1·06 Siemens unit, and that a current of 1 ampere deposits in one hour 4·025 grains silver from an aqueous solution of silver nitrate. It is to be taken as provisional, and can only be regarded as final when the pending work on the practical units of electrical resistance and atrength of current is finished.

Digitized by Google

electrolysed for six hours by a current not exceeding 0·2 amperes introduced by two pieces of platinum foil of about 50 sq. cm. surface suspended in the liquid. The liquid having cooled over night, litmus is again employed to test whether any acid has been formed during electrolysis. In that case the boiling with zinc filings must be repeated, and the solution again electrolysed by weak currents. During this whole treatment care has to be taken that the concentration of the solution remains approximately constant. It is, therefore, well to cover the vessel containing the solution with a glass plate, so that but little water vapour can escape. As soon as the solution is sufficiently free from acid and iron it is filtered off. To each litre of the filtrate about 50gr. of mercuric sulphate, free from acid, are added and well stirred. The mercury salt will in general assume a yellow colour after long standing. If the solution has stood for a day, and a portion of it, on being shaken up with more mercuric sulphate, does not turn perceptibly yellow, the solution may be filtered off and concentrated in a flat porcelain dish over a water bath. Here we must take care that the crystals do not form at too high a temperature, as otherwise they easily lose a portion of their water of crystallisation. To secure this the flame under the water-bath is extinguished, and the dish left in position covered with a glass plate. If after further cooling no crystals are separated, further concentration is necessary. If the heating was too protracted, and the crystals were formed under unfavourable conditions, a little water must be added and the whole warmed until everything is redissolved. The concentrated solution is poured off, and either further evaporated or kept for future use. The last traces of the solution are removed from the crystals by letting the dish stand for some time in a slanting position. It it is not advisable to sharply dry the crystals, as they thereby lose water of crystallisation. For the same reason they must be kept in a closed vessel.

Sulphate of Mercury.—The mercuric sulphate used must not be coloured yellow by a basic salt. If that should be the case, stir up one part of the salt with two parts distilled water, and add, constantly stirring, so much of a solution of one part mercuric sulphate to 1,000 parts of water as is necessary to make the colour disappear. Then pour off the liquid and wash the paste several times with distilled water, but without thereby causing another yellow colouration. If the sulphate is white to begin with, and only shows a faint yellow colouration after considerable time on shaking up with distilled water, it may be used at once. If this colouration is not shown on shaking up with water, the salt must be washed out several times with distilled water until the first traces of yellow colouration appear. If the salt had to be wetted for cleaning, the water should be driven off as much as possible by mechanical means. If dried by heat the yellow colouration will reappear. In order not to have to keep the wet salt only so much salt should be treated by the above process as is necessary for the purpose in hand.

To prepare the paste, two parts of the sulphate should be added to one part of mercury. If the sulphate was dry, it should be stirred up with a paste made of zinc sulphate crystals and concentrated zinc sulphate solution until the whole forms a stiff mass everywhere permeated by zinc sulphate crystals and small globules of mercury. But if the sulphate was wet, only zinc sulphate crystals should be added, taking care, however, that they are in excess, and are not dissolved even after prolonged standing. Here, also, the mercury must permeate the paste in small globules. It is well to crush the zinc sulphate crystals a little before using, so that the paste may be more easily manipulated later on.

Details of Construction.

For the preparation of cells containing mercury as the positive electrode, the following details should be attended to :—Before introducing the hot zinc amalgam place the glass vessel, well cleaned and carefully dried, into a hot water bath. Then pass a suitable thin-walled glass tube through the neck of the vessel on to the bottom of the branch which is to contain the amalgam. The tube ought to be as wide as is consistent with the dimensions of the vessel. It is intended to protect the rest of the vessel from contamination. The amalgam is introduced by means of a glass tube about 10cm. long drawn out into a point, the other end being provided with an indiarubber tube about 3cm. long closed by a short glass rod. The point of the tube is inserted below the surface of the liquid amalgam heated in a dish, and a portion of the amalgam is sucked into the tube by compressing and releasing the indiarubber. The point is then quickly freed from external impurities derived from the surface of the amalgam, introduced into the cell through the wide tube, and emptied by pressure on the indiarubber. The point ought to be so fine that the amalgam does not issue except on pressing the rubber. The process is continued until the branch contains the required quantity of amalgam. The vessel is then taken out of the water-bath. After cooling the amalgam should adhere firmly to the bottom of the vessel and exhibit a bright metallic surface.

To introduce the mercury and the paste a suitable funnel with a long tube is used. The paste should not touch the upper walls of the vessel, but may be pushed in with a glass rod if too stiff to flow.

Before pouring in the zinc sulphate solution the paste and zinc amalgam should be covered with zinc sulphate crystals, these prevent a creeping up of the paste after wetting with solution. In filling, the zinc sulphate crystals and the liquid should not contain large air-bubbles. These may be removed by knocking.

If the cell is to contain amalgamated platinum foil as the positive electrode, the amalgamation may be performed as follows:—The cell vessel is first filled with aqua regia and heated in a sand-bath until a rapid development of gas takes place at the platinum. Then rinse with water, pour mercury into the branch intended to contain the zinc amalgam, and fill the entire vessel with a concentrated solution of mercurous nitrate containing a little nitric acid. Then connect the mercury with the positive and the platinum foil with the negative pole of a battery, and send a current of about 0·5 ampere through the solution until the platinum foil is covered over with firmly-attached mercury globules. The whole process lasts about five minutes. Finally the vessel is thoroughly rinsed with distilled water until not a trace of the nitrate remains.

The zinc amalgam is introduced with the precautions mentioned. After cooling, it is covered with zinc sulphate crystals, to which concentrated zinc sulphate is added after filling until the whole forms a paste. The vessel is let stand for two days, so that the crystals are closed up and form a layer impervious to the paste. Then the whole vessel is filled up with the latter.

The following points should be specially borne in mind in the construction :—

1. The mercury intended to serve as positive electrode must be kept rigidly free from contamination by more positive metals. Special care should be taken that no portion of the zinc amalgam comes into contact with the mercury.

2. The cell should always be so arranged that at all temperatures the whole electrically active surface of the electrodes is in contact with zinc sulphate solution concentrated for the temperature in question. Hence during the process of filling crystals should be added in such quantity as to ensure their presence in excess even at the highest temperatures which the cell may attain.

3. The zinc sulphate used must not contain free acid. For in the thing the E.M.F. of the cell is affected by it, and, on the other hand, the circuit of the cell may be broken by hydrogen developed at the zinc. For the gas produced cannot escape through the zinc sulphate crystals, but collects underneath them, and finally pushes them up, thereby interrupting the connection between the zinc and the zinc sulphate.

For easy and safe handling the cell is attached to a metal case which may be closed and placed in a petroleum bath. Its lid is provided with two binding screws, each of which is joined to one of the electrodes ; the bottom is perforated, so that the cell is surrounded by the petroleum. To determine the temperature of the cell, a thermometer must be enclosed in the case whose scale can be read from outside. The best plan is to fuse a thermometer into the glass stopper, as shown in the figure, so that the bulb penetrates as far as possible into the cell and the scale projects through the lid.

Cells of this pattern are being constructed by Herr R. Fuess in Steglitz, near Berlin, and may be tested and certified at the Reichsanstalt at the option of purchasers.

PARLIAMENTARY INTELLIGENCE.

ELECTRIC POWERS PROTECTION CLAUSES.

TUESDAY, JUNE 27TH.

Mr. PEMBER addressed the Committee on behalf of the National Telephone Company, urging that in the future there might be very many uses to which slight electrical currents with earth returns could advantageously be put, but at present there were only two : the telegraphs and the telephones. He dwelt upon the importance and the extent of the telephone service, with its 218 million messages, and said that if the tremendous incubus of expense of doubling the wires was put upon the Company the price of telephony to the public must be increased, while in the public interest the additional overhead wires would be disadvantageous. With the telegraphs and telephones, who were the first in the field as users of the earth for electric circuits, the currents were so low as to do harm to nobody else. The telegraphs were protected by the veto of the Postmaster-General, and it was only reasonable that the telephones should also be protected. It was suggested that metallic returns were best for the telephone companies themselves, which theoretically and scientifically might be true, but there was, he contended, no marked superiority, seeing that in towns where the National Company had been in competition with the Post Office working metallic returns they had been able to increase their business. The metallic circuit system could only be adopted if they were let alone and without disturbance. The suggestion was also made that the telephone clauses had checked the growth of electric traction in

Digitized by Google

England, and so deprived the public of the benefit to be derived from it. Even if that were true he should still urge that the clauses should be upheld. They had in the telephones and the electric traction two very great benefits to the public, of which, he suggested, the telephones were not now, and would not be in the future, by any means the slighter of the two; and he should say that it was not right to oust one set of undertakers for another when those to be ousted were prior in time, and had the legal theory of innocuous user so completely on their side. But he maintained that the clauses had not deprived the public of the benefits of electric traction, inasmuch as there were 70 cases in which tramway companies or corporations had power to work by electricity, but had not adopted it. It would not make the rate of traction cheaper, or progression speedier. The advocates of electric traction contended that they could not completely insulate. To that his answer was that they had better go and learn how. Far greater difficulties in connection with electricity had been overcome by science, and he advised them to go and overcome that difficulty, together with their present inability to do without the hideous disfigurement of the overhead trolly, for he maintained that they would not be allowed to use electrical traction in England on any great scale until they had got rid of the latter difficulty, and ought not to be allowed to use it until they had got rid of the first difficulty. All the difficulties in the way of underground tramway communication could be got over as they had been done at Buda Pesth, and after all that science had done it was simply ridiculous to suppose that she was going to be beaten by mud and damp and falling nails. The traction companies wanted, as Major Cardew had suggested, a little mild compulsion, and that compulsion should be in the form of saying that they should not use the earth for those currents, and thereby hurt other persons. If they were not forced to make the necessary improvements they would not do so, and would go on to the end of the chapter and say that they could not. The policy of Parliament had been the right one hitherto of placing restriction both upon electric lighting companies and tramways; the Government, by its veto, could take care of the Post Office telegraphs and telephones, and he asked that Parliament should continue its protection to the National Telephone Company. As to what should be done in the way of legislation the telephone companies would be quite content with the continued insertion in all tramway Acts of the Plymouth Clause. He could not, however, shut his eyes to the fact that the Committee might interpret their instruction to mean much more than a declaration of what ought to be done between existing parties. They might think that in future there might be a dozen or a hundred uses of which as yet nothing was known to which delicate currents with earth returns might be put, and it might be wise to safeguard those by general legislation on the ground that prevention is better than cure. It might therefore be done by enacting that in no case should a current be sent to earth, never mind who by, greater than some ascertained fraction of an ampere; and as to what the limit should be there would, of course, be scientific evidence taken as to the point at which currents harmful to others might be said to begin. That, however, would not cure induction, and for that purpose it might be enacted that the two wires should be laid so near as to prevent induction. To meet the difficulty of insulation not being absolutely practically perfect, he suggested that the principle of the clause which compelled railways to consume their own smoke should be followed, providing that it should be a sufficient compliance with the Act if the promoters in the construction and maintenance of their works and the working of the tramway from time to time adopt the best known means of insulating the conductor and other electrical works to prevent injurious interference by induction or otherwise with other electrical circuits.

Mr. MOULTON (on behalf of the Railway Companies) said that in the course of electric lighting legislation the companies had been placed under terms which entailed upon them a greater task than the traction companies had of conducting their operations so as not to injure others. The change of front on the part of the traction companies did not mean that electricity had grown more timorous or more weak. It was a struggle not on behalf of electricity generally, but on the part of one rich interest to extend in England an imperfect, early, and undeveloped system, which would give more trouble to get rid of than it would do good so long as it lasted. They asked for the indulgence of being allowed to use currents of very great intensity and magnitude, being the output of engines of many hundreds of horse-power taking no precaution to prevent leakage to earth; on the contrary, using that leakage as a means of assisting the return of their current, thereby throwing serious damage and responsibility on all their neighbours. The reason they asked to do that was that they might extend a cheap system of traction of the very earliest and crudest form, and if they were allowed to do it it would have the result of keeping all better systems out of the market for all time. The double insulated return, he maintained, would not throw a large extra expenditure upon the traction companies. As to the question whether they would be able to bridge over the gap of 14ft. with the underground conductors, he did not believe a single engineer who had been called who, if offered a premium of £500, would not be able to think out something to get over that difficulty. The only system which asked for the indulgence was the single overhead trolly system; but that was not the only form of traction existing. The best system in England was that at Birmingham, where they used accumulators on the car and ran without interfering with anybody. He did not see why the single-trolly system should be allowed to compete on unfair terms with other systems which worked without damage to anyone. Electric traction did not need the indulgence asked for, either by accumulators or by the double system underground or above ground; it could be done without. We had not yet exhausted invention, and he knew many methods which had been suggested which would have a chance if the cheap and nasty system of single overhead wires was not permitted. He dwelt at length upon the inconveniences and dangers to which the railway working was exposed at present, and urged that the cost of preventing those dangers, so far as they could be prevented should not fall upon the railway companies. He asked that which had been given in the Bolton case should be given as a regular thing, viz., that the promoters should so construct and maintain their electric circuits and so work their tramways in all respects as to prevent any injurious effect by leakage or induction with the railways signals and telephonic apparatus; and that before electricity was used on any tramway the Board of Trade should certify whether any and what works or appliances were required on the Railway Company's premises, for the purpose of preventing any interference; the Railway Company to execute such works, and the cost of executing and maintaining them should be paid by the promoters. They also asked for a further clause, "If in the construction working, use, or maintenance of said tramways or other works of the promoters, the telegraphic communication is interfered with, the Railway Company may execute and maintain such needful and proper works as may be reasonably necessary for remedying or obviating the disturbance, and the promoters should afford to the authorised officer of such railway company all reasonable information and facilities for the purpose of enabling them to ascertain the cause of such interference and disturbance." Then there was a proviso at the end, "Nothing in this Act shall exonerate the promoters from any action, indictment, or proceedings for nuisance in the event of any nuisance committed by them in the exercise of any powers for the use of electricity conferred upon them by this Act." Those were the clauses which he asked the Committee to insert for the benefit and protection of the railway companies.

Mr. BALFOUR BROWNE then addressed the Committee on behalf of Municipal Corporations in England and Scotland, 12 of which he said he represented. Those corporations owned something like £2,000,000 worth of tramways, and even where they were not at present the owners they could become so by purchase. In all the interest of the tramways were represented by 15 million solid sovereigns, whereas the telephones represented only 3½ millions, not of solid sovereigns, but a great many of them paper sovereigns. The Telephone Company spoke of their 218 millions of messages, but against that there were the 500 millions of passengers by tramways. Therefore he urged that tramway traction was of far more importance to the public than the telephones, and that the telephone clauses really stood in the way of electric traction. He referred to the experience of Salford, Birmingham, and Glasgow. The Committee would have to choose between the two, for Mr. Sinclair had declared that the continuance of the telephones debarred any increase of electric traction. If it were a question between telephones and tramways, he urged that the people would choose the tramways, and characterised the use of telephones as the luxury of people who wanted to indulge their idle hours by hearing other people's conversation. The telephones, even without tram traction, would have to adopt metallic returns for their own protection. The exchanges at Johannesburg and Pretoria had metallic returns, and were in advance of England; the exchanges which the Government were putting up in India were all metallic returns; the exchanges in Australia, put up on the single-wire system, were in all the large towns being changed into metallic returns, while the Government had declared that in future they would not grant any licenses for telephones unless they had metallic returns. The fact was that the telephones were not complete or perfect until they had a metallic circuit, and whatever the tramway companies might do it would be impossible practically to insulate so as not to interfere with the telephones.

THURSDAY, JUNE 27TH.

With regard to the railways, Mr. LANGDON thought that even if there was no electric disturbance at all from the tramways there ought to be a metallic return on the railway signals. And he said, "That is the advice that I would give to my Company." What did he want to insulate the tramways for? merely to give him what they called a second line of defence. This second line of defence which they desired at an enormous expense to the tramway companies was absolutely unnecessary so long as their insulation continued perfect. Passing from the railways to the question of the electrolytic action on pipes: the whole of this arose from an unguarded, and perhaps the only unguarded, expression used by Mr. Preece. It was all nonsense; the electrolytic action did not exist. The water companies and the gas companies knew quite well about this inquiry, and they did not ask to be heard before the Courts at all until Mr. Preece said that he thought the question of electrolytic action on water pipes was serious. Mr. Hesketh said "We have had reason during the past month to take up all the main streets of Blackpool for the purpose of laying down electric lighting conduits, and in no instance have I seen any evidence of electrolytic action, although I paid particular attention to the matter." The one case of electrolytic action that was quoted against them was the case of Preston, and was disposed of by Major Cardew. Under these circumstances was there anything in that electrolytic action case. This was not a question of electric traction against all the world, it was a question of the telephone against the world. The remedy was obvious; to get efficient telephones they must have metallic circuits.

Mr. CRIPPS then addressed the Committee on behalf of the Traction Companies. Their desire would be to give what assistance they could towards formulating such a clause that all parties might be reasonably protected. He should like to say a word about a misapprehension that seemed to have arisen. Talking of the traction companies, they had never used the earth return, and did not desire to use the earth return. The question was not between the earth return and the metallic return, but it was a question really between the insulated and uninsulated metallic return. And this was really carrying out Mr. Preece's suggestion. The clause they proposed was: "The Company (that was the traction company) shall use metallic returns," therefore there was an obligation in their form of clause upon the traction companies to use the metallic return as contrasted with earth return, "and in working their system shall take such reasonable precautions as the Board of Trade may direct for preventing interference with any properly constructed insulated metallic circuit of any railway or telephone company, and for preventing electrolytic action

Digitized by Google

on gas or water pipes." The basis of their clause was that railway and telephone companies should use a properly constructed insulated metallic circuit, but if they did, their subject to the directions of the Board of Trade to work their system under such conditions that they did not interfere either with the railway system or with the telephone system, and also under such conditions as to prevent any electrolytic action on gas or water pipes. They did not believe there was the least difficulty as regarded the electrolytic action on gas and water companies. They were willing to come under the obligations to follow any directions required by the Board of Trade to prevent electrolytic action on gas or water pipes. What they desired to see, and that was the intention of the clause, was a proper protection as between parties seeking for special statutory powers in relation to these great public objects. Mr. Preece and all the other witnesses had stated the same, stated that the best system of telephonic communication was the metallic circuit return; that was the proper remedy, and that was the remedy for which the clause provided. If the committee were to come to the conclusion that the telephone system or the railway signalling apparatus was not to be insulated, there was an end to traction. The telephone companies objected that there would be great interference in changing from the earth-return system to the metallic-return system. The complete and absolute answer to that was that they were doing it in London. There was no traction company interfering with them in London, and yet for their own purposes, throughout the whole of the London district—500 square miles Mr. Gaine had told them—they were substituting the metallic-circuit returns for the earth-return system. And then on the question of expense, they knew that the National Telephone Company had a metallic-circuit return in Hull and Newcastle, where a subscriber was charged £10 a year. In London, where they had the earth-return system, admittedly not the best, the charge was from £17 to £20, and they were bound, apart altogether from the question of traction companies, to introduce the better system.

Mr. POPE then addressed the Committee on behalf of the Gas and Water Companies. He said the clause proposed by Mr. Cripps might be paraphrased thus:—"That this Committee recommends that the Traction Company do what they are doing, and that the question of what restriction is to be imposed upon them should be referred back to the Board of Trade," and he could not help thinking that it was an ingenious method of tempting the Committee to give practically no clause at all. He would ask them definitely to recommend that in all future grants of statutory powers to use electricity insulated metallic returns should be required as a condition of that user. He maintained that the dangers from electrolytic action and corrosion were very serious, and submitted the following clauses to the Committee:—

"(A) The undertakers shall not make use of, or permit to be used, any conductor other than an effectively insulated conductor for carrying any supply of electricity from or to the generating station; nor shall they in any manner connect, or permit to be connected, to earth any part of any circuit except for the purpose of testing or indicating.

"(B) The undertakers shall employ all practicable means for preventing, detecting, and, as soon as practicable, stopping any leakage of the electric current to earth.

"(C) The undertakers shall not use or employ, or permit to be used or employed, any gas or water mains or pipes as conductors, for the purpose of completing any electric circuit or for the conveyance of electric current.*

"(D) Nothing in this Order contained shall prevent the undertakers from being liable to an indictment for nuisance, or to any other legal proceeding to which they may be liable in consequence of generating, using, or supplying electric currents.

"(E) The undertakers shall compensate every person who suffers any damage by reason of any failure to observe the provisions of this Order, or caused, without any default on his part or on the part of persons for whom he is responsible, by an electric current generated, transmitted, or employed by the undertakers."

Mr. WALLACE (on behalf of the Electric Lighting Companies) asked the Committee to exempt the Electric Lighting Acts altogether from any operation of any clauses that the Committee might require to be inserted in any general Bill. The position of the electric lighting companies had been definitely settled. There was a Committee in 1882; there were the Electric Lighting Acts of 1882 and 1888; and the very extensive inquiry held by Major Marindin, in which the nature of the supply of electricity that was to be allowed to the electric lighting companies was thoroughly gone into and settled once for all.

The CHAIRMAN said the Committee would meet again to discuss the matter, and, if necessary, would communicate with Mr. Wallace, and he should have the right of appearing.

This concluded the proceedings, and the Committee adjourned till Thursday, when they will confer in private.

* (This is copied from Section 29 of the Gasworks Clauses Act, 1847.)

Uni-Directional Currents Obtained from Alternating Currents.—An attempt to obtain a commercial solution of this important problem, satisfactory enough to enable the rectified current to charge a storage battery, has been made by M. Pollak, who has communicated his results to the Académie des Sciences. M. Pollak uses a synchronised commutator in conjunction with an interrupting device for preventing discharge from the storage battery when the rectified voltage falls below that of the battery.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June* 23, 1893.

Small Central Stations.—Attention is being directed to the fact that small central lighting stations in the United States with very few exceptions are financial failures. Several reasons have been advanced to account for this, but it is doubtful if even the most favourable conditions would put the majority on a paying basis. The truth of the matter seems to be that in the earlier days of electric lighting the popular craze for electrical speculation, united with the American desire to be up with the times, rendered the specious claims of selling agents irresistible, and apparatus was bought and stations erected with scarcely any argument in favour beyond the all-powerful one that "electricity is the coming thing." Several syndicates have been formed which are purchasing non-paying stations for but a small percentage of the original cost, thoroughly over-hauling them, and, by placing them on a thorough engineering and business basis, are earning good dividends on their investment. In a few years we may expect the same unsatisfactory state of affairs in regard to the hundreds of electric railways now being built with no real prospects of financial success.

A New Conduit Electric Railway System.—An experimental conduit electric railway is being exhibited at Coney Island, the summer resort near New York. A flexible shoe 7ft. 6in. long, secured underneath the car, enters through a slot into a conduit. At intervals of about 6ft. in the conduit are boxes, from which project an arm at right angles; when the shoe strikes the arm, the latter is moved forward, and by means of a brush inside the box makes connection with the supply line, the current passing to the metallic side of the shoe by means of sliding contact with the end of the arm. The boxes containing the contact brush and mechanism are filled with a liquid insulator and so designed as to avoid leakage, even if the conduit should be flooded. The only connection with the supply line at any one time is through the two boxes opposite the shoe, and it is claimed that leakage is thus reduced to a minimum, the insulation in all of the other boxes being practically perfect. The shoe is flexible and easily admits of going around sharp curves, and is automatically released from the car if the latter should be derailed.

The Electrical Fountains at the World's Fair.—It is reported that the electrical fountains at the World's Fair are far from being successful.

CORRESPONDENCE.

CONTINUOUS CONTROL OF ELECTRIC LIGHT CABLE SYSTEMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I take the liberty to inform you that the remarks Dr. Kallmann published in No. 784 of your esteemed journal on my methods of finding faults in the network of central stations during the working of the plant do not agree with the facts.

Dr. Kallmann says: "In admitting that his methods are useless, if the middle wire be earthed at any point, Dr. Frölich has shown the inapplicability of his plan to nearly all central-station networks, as in nearly all cases the insulation of one pole is more or less negligible."

First, it is to be answered, that my methods, in the form published in your journal February 10th, 17th, 24th, 1893, are still very easily applicable when the insulation is very low; for instance, about one ohm. Whereof, these methods are directly applicable to all central stations whose middle wire is not really earthed, *i.e.*, to most cases of central stations at large.

If the middle wire is really earthed, it is true these methods are not directly applicable; but they can be made so by a very simple contrivance, viz., by *placing the system of testing or pilot wires instead of earth* in the diagrams of my methods. Hence, my methods of taking insulation and finding faults extend to all parts of the network where testing wires are laid, even when the middle wire is really earthed.

Digitized by Google

Dr. Kallmann's methods are applicable only as far as testing wires are laid. Now, in all cases I know of, testing wires are not introduced into the houses, but are laid with the street cables only. Now, most faults happen to occur in houses, and just these faults are not detected by Dr. Kallmann's signals. My methods show faults even in the houses, when the middle wire is not really earthed. If the latter is entirely earthed, it will probably be impossible to find faults in the houses by any measurement, and that will be the reason, I think, why, in this case, testing wires *must* be introduced into the houses.

Dr. Kallmann remarks that my methods "entail the expenditure of much time and material." In saying so he omitted to state that, after my methods, all necessary measurements can be taken by the telephone, viz., by the very simplest instrument.

It is true that it is easier and takes less time to observe the automatic signals of Dr. Kallmann, instead of applying my methods. However, faults are only detected by Dr. Kallmann's signals when they are obnoxious to the plant itself, or to neighbouring plants, while my methods allow a daily survey to be taken over the insulation in all parts, and to determine faults long before they grow obnoxious.

In concluding, I beg to remark that Dr. Kallmann's signals do not show faults when they have already spoiled the telephonic intercourse in the neighbourhood, earth being used in the telephonic circuit; for it has been stated several times by officers of the Berlin Telephone Service that in case faults arise suddenly in the central station, hundreds of telephone annunciators fell, while Dr. Kallman's signals remained untouched.—Yours, &c.,

Berlin, June 21, 1893. O. Frölich.

SINGLE-PHASE ALTERNATE-CURRENT MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The course which has recently been taken by the controversy as to the priority in the field of single-phase motor construction induces us to send you the following statements, hoping that you will give them publicity in your columns.

After the publication of a description of his new alternate-current motor, by Mr. C. E. L. Brown, Herr von Dolivo-Dobrovolsky tried to show that such motors were entirely useless in practice. While Herr Arnold, of the Maschinenfabrik, Oerlikon asserted that the motor of Mr. Brown was nothing new at all, but had been known for years.

Now, since both of these assertions have been discredited, Herr Behn-Eschenburg, also of the Maschinenfabrik Oerlikon, discovers that he himself invented this motor (which, according to Arnold, had long been known) *as early as the summer of 1892*, and that Brown has simply copied it.

The following lines will, however, set right these assertions in a very simple manner:—If Herr Behn-Eschenburg were acquainted with the tests carried out in Oerlikon he would know that as early as 1890 and 1891 Brown had already ascertained, in the course of his experiment, that multiphase motors may be ran and even started with only two phases just as well as with three. He also showed that multiphase motors when once started continue to run with one phase only, although in consequence of their not being designed for it they gave but little power. Nevertheless, the present alternate-current motor of Brown may be said to have been invented in these experiments.

After the founding of this firm, we took up energetically the further development of these observations. *In October, 1891*, we received from Herr Oscar von Miller inquiries for the electrical station at Furstenfeldbrück. This had been intended by Herr von Miller to be on the rotating current system; we tendered for the supply of alternate current, since we declared ourselves in readiness to supply alternate-current motors as good as those for rotating current "which will start themselves, and possessing neither collectors nor sliding contacts." In answer to a question from Herr von Miller as to how the motors were started, we wrote to him, "the starting is effected without commutation of the current by artificially-produced difference of phase." At the same time we sent to Herr von Miller a drawing of such a motor showing Brown's short-circuited rotating part exactly as he constructed it in his multiphase motors.

On November 27, 1891, we sent in our proposals for the electrical station in the town of Chur, for which installation we similarly proposed simple alternate current on the grounds "that we have succeeded in constructing electric motors for ordinary alternate currents which compare equally with those for direct current as well as those for multiphase alternate current." In the description of the motors the proposal runs as follows:—"We supply electric motors for alternate current, which have the peculiarity that they possess neither collectors, brushes, nor sliding contacts." Almost the same sentence is to be found in our tender for Ragaz, dated February 2, 1892. For all these stations the Maschinenfabrik Oerlikon had tendered rotating-current systems, and it is principally to be ascribed to our proposals that they were carried out with alternate current.

Herr Oscar von Miller in January, and the promoters of the Ragaz station in February, 1892, had seen such a motor at our works. In the following months such motors were shown by us to a great number of visitors to our works, among whom were many very prominent electricians.

All this is not affected by the circumstance that in the summer of 1892 we had also taken up the construction of synchronous motors for the same reason which appears to still prejudice Herr Behn-Eschenburg against the non-synchronous type. We hoped by the use of synchronous motors to reduce the idle current. Our experience shows us, however, that this desirable result cannot, under the conditions which obtain in practice, be attained with this type of motor, while we have succeeded in so improving the non-synchronous motors that their idle current is remarkably small and that they will start with a moderate increase of current.

From the above it will be readily seen that Mr. Brown did not wait for Herr Behn-Eschenburg, nor till the summer of 1892. We will therefore leave it to the reader to judge of the accusation brought by him against Mr. Brown.

We hope you will find room in your columns to give publicity to these statements.—Yours, &c.,

June 30, 1893. Brown, Boveri, and Co.

ROTATING FIELDS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I observe that in your editorial note on page 56 of your issue of May 19th, you trace the rotating field to the well-known Ayrton-Perry motor. So far as my memory serves, this motor was brought out in 1882 or 1883; but the rotating field is really much older. The motors of Bürgin and of Borel, shown at the Paris Exibition of 1881, were really rotating field motors, and so were the old Froment motors designed a quarter of a century ago, or thereabouts, and used largely for the rotation of Geissler tubes.

The invention of these rotating field motors was generally ascribed to observation of the deflection of the galvanometer needle. It was observed that by making the needle heavy and passing a momentary current through the coil constituting the field, the needle might be deflected more than half a revolution. Then by reversing the current, or, in other words, rotating the field through an angular distance of 180deg., the needle could be deflected through another half-revolution, and so on, a continuous rotation being produced. In some of Froment's motors the field was rotated in this manner through widely differing angles at a time—120deg., 90deg., 60deg., and even less in some cases, according to the number of coils. Hence we had a crop of such moters, mostly with wireless armatures differing but little from the galvanometer needle, except in being heavier and thicker and, as a rule, with extended pole-pieces. A large number of the electric secondary clocks produced during the last 20 years, have had motors of this type with which to drive the working parts.—Yours, &c.,

Chicago, U.S.A., June 18, 1893. J. G. Lorrain.

SUBMARINE CABLES TRUST.—Notice is given that on and after tne 14th inst., the sum of £1. 10s., balance of the coupon due April 15th last, will be paid by Messrs. Glyn, Mills and Co., 67, Lombard-street, E.C. The coupons should be left three clear days for examination.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Directors of the Electricity Supply Company for Spain (Limited), invite tenders for the supply and erection of machinery, &c., required for the extension of their works in Madrid. Further particulars appear in our advertisement columns, and plans, statement of requirements, &c., may be obtained at the offices of the Company, 15, St. Helen's-place, on and after Monday next, 10th inst. Tenders must reach the Secretary, Mr. P. A. Latham, before 11 a.m., on July 29th.

——— The Secretary of State for War invites tenders for the purchase of a quantity of old metal. Tenders have to be in to the War Office by 12 o'clock noon on Wednesday, the 10th inst., addressed to the Director of Army Contracts.

——— The Municipal authorities of Ostend invite public tenders for the electric lighting of the town, which must be in by September 15th.

——— The Corporation of Launceston (Tasmania) invite tenders for the supply and erection of electric lighting plant, and for the maintenance and working of the installation for six consecutive months. Tenders are to be in byDecember 30th next.

——— The Electric Lighting Committee of the Lancaster Corporation invite tenders for the erection of a brick chimney, 120ft. high, to be built in the Corporation yard, Maston-street. Tenders must be in by the 15th inst.

TENDERS RECEIVED.—Six tenders have been received by the Municipal authorities of Liège for the electric lighting of the town. One is sent in by MM. Van Rysselberghe and Moris (Antwerp), one by Messrs. Siemens and Halske (Berlin), one by M. J. Jaspar (Liège), and three by M. Pieper (Liège). The amounts varied from £20,000 to £52,000 for the work of installation, and the charge for the supply of current varied from 5d. to 7d. per kilowatt. The Municipal Authorities have not yet accepted any of the tenders.

——— The following were the tenders sent in for the electric lighting of the Holborn Town Hall, that of Messrs. Verity and Sons being accepted (as stated in *The Electrician* last week):—Messrs. Hulett and Co. (Limited), £585; Messrs. R. S. Hughes (Limited), £548; Messrs. Verity and Sons, £400.

——— The Paddington Baths Commissioners have received the following tenders for fitting up the baths with electric light apparatus:—Mr. Sclater, £85; Messrs. Southerley and Ridout, £72; Messrs. Dawson and Hammond (accepted), £75.

APPOINTMENTS VACANT.—The Council of the Borough of West Ham invite applications for the appointment of electrical engineer, who is to prepare plans and specifications and superintend the work of the installation to be carried out in the borough, and to advise the Council generally on electrical subjects. The salary would be £250 per annum, and applications must be in by five o'clock on Monday, July 17th, to Mr. Fred. E. Hilleary, the Town Clerk, Town Hall, West Ham.

——— Mr. J. C. Sharman, Assistant Electrical Inspector at Liverpool, having resigned his position, the Electrical Sub-Committee of the Corporation Watch Committee have been instructed to take steps to fill the vacancy.

REMOVAL NOTICE.—Mr. T. Harding Churton, of Leeds, has removed his works and stores from South-parade to Park Cross-street, Leeds. The office address is still 5, South-parade.

MESSRS. J. AND W. WEEMS.—This firm have opened an office in London at 22, Billiter-street, E.C.

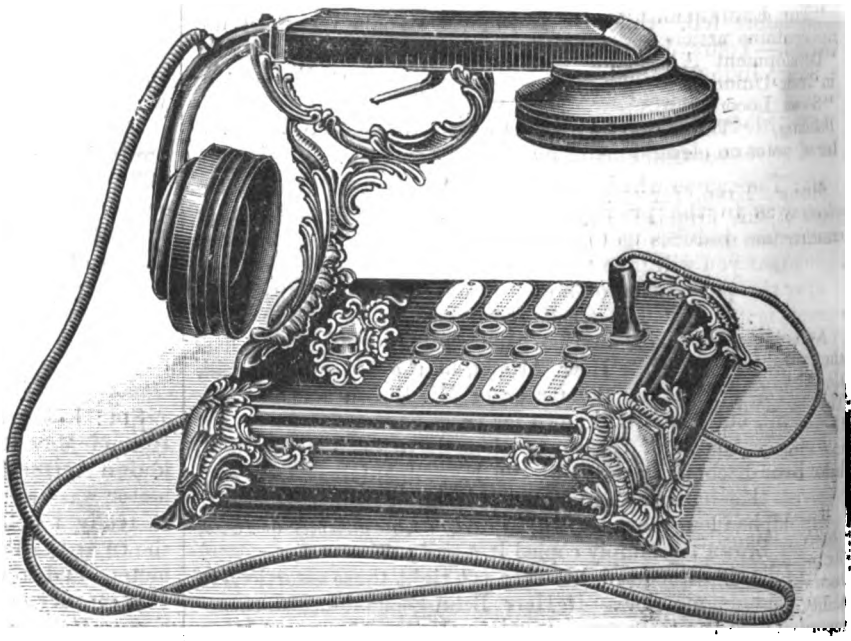
DISSOLUTION OF PARTNERSHIP.—Messrs. Appleton, Burbey, and Williamson, electrical egineers, have dissolved partnership. Debts will be paid by Messrs. W. T. Burbey, A. E. Williamson, and E. L. Joseph, who continue the business.

AUCTION BIDS BY TELEPHONE.—An instance of the commercial usefulness of the telephone was recently shown in Liverpool, where the bidding at an auction of some building society shares was carried on between some gentlemen present and a telephone subscriber, who was made acquainted with the rival offers through the auctioneer's instrument, and eventually secured the shares.

NOTTINGHAM EXHIBITION.—Firms desirous of securing advertisement space in the official catalogue of this Exhibition are requested to communicate with Messrs. R. Allen and Son (Limited), Caxton Works, Nottingham. The Exhibition is organised in honour of the British Association Meeting.

ELECTRICITY IN MINING.—At the meeting last week of the Tolima Mining Company (Limited), the Chairman mentioned that the installation of the electric light had greatly added to the returns by enabling more work to be done. The surface and engine works, and the underground work, as far as the bottom level, are lighted by electricity, and the various departments are in telephonic communication with each other.

COMBINED TABLE TELEPHONE AND SWITCH.—We illustrate herewith a compactly arranged table telephone and switch, which has been designed by Herren F. Butzke and Co., of Berlin. The illustration shows the simple manner in which communication can be held with different branches of an office or a factory by placing



the movable connection over the particular orifice required. The bell is not shown, being on the under part of the stand, beneath the push. The stand is made of walnut, with metal fittings, and the whole forms an ornamental adjunct to the table, and takes up but little space.

BIRMINGHAM TELEGRAPH FACTORY (LIMITED).—On Thursday Judge Chalmers delivered judgment at the Birmingham County Court with respect to the petition for the compulsory winding-up of this Company (in voluntary liquidation). His Honour had reserved judgment pending the consideration of the question whether some shares allotted to the Directors as nominees of Fowler, Lancaster, and Co. (Limited) made these Directors liable as contributaries to the estate of the "Factory" (*see* last week's *Electrician*). His Honour decided that the shares in question had been paid for in cash within the meaning of the Act, and that being so there was nothing to be gained by a compulsory order, which would greatly increase the costs, and the petition (which was presented by Messrs. H. Alabaster, Gatehouse, and Co., of London) would, therefore, be dismissed with costs.

HARTMANN AND BRAUN.—We have received a catalogue of the electrical instruments exhibited by this firm at Chicago A useful feature is the clear statement of the deflection of each of the many galvanometers described, in terms of the current required to give a deflection of one millimetre at one meter distance.

ELECTRIC LIGHT ILLUMINATIONS FOR THE ROYAL WEDDING.—Messrs. Berry and Harrison inform us that they have fixed a

Digitized by Google

Brunswick Star, 8ft. 6in. in diameter, fitted with over 400 16 c.p. lamps, at the *Morning Post*, taking upwards of 200 amperes. The peaks of the star are clear lamps, the inner ring coloured amber, and the monogram "G. M." in red and green. The supply is being obtained from the Metropolitan Electric Supply Company, and the whole work has been done under three days. They have also constructed a "Prince of Wales's Feathers," and monogram "G. M." for the Hotel Windsor; this consists of over 200 clear and coloured lamps, taking about 90 amperes, the supply coming from the Westminster Supply Company.——Messrs. Frank Suter and Co. supplied the illumination for the Albemarle Hotel, Piccadilly, and for Messrs. A. and F. Pears (Limited), Oxford-street. In the former some 750 incandescent lamps were employed, and in the latter 300 incandescents and 10 arcs, the display in each case being most effective.——The Edison and Swan Company displayed at their head office, in Victoria-street, an immense radiating star, bulging to a central circle enclosing the letters "V. R." and "G. M." The star was 50ft. in circumference, and was built up of a thousand 8 c.p. incandescent lamps of various colours. The current was supplied from Deptford by the London Electric Supply Corporation by special leading wires from their mains.

Messrs. Rashleigh, Phipps, and Co.—This firm supplied for the illuminations on Thursday some unique designs in electric lighting work for a number of London houses. The firm has been very busy for some time past, and send us a list of a large number of installations carried out by them, including private houses, business premises, temporary lighting, &c., showing a total of nearly 4,000 lights. On Saturday last the *employés* of the firm held their annual holiday at Brighton.

"The Engineering Magazine."—The July issue of this magazine contains articles on the "Limits of the Natural-Gas Supply," "Development of the Modern Steam-Pump," "Weak Points in Trade-Unionism," "The International Engineering Congress," "Steam Locomotion on Common Roads," "Mechanical Aids to Building," "The Safety Car-Coupler Problem," as well as a number of notes on electrical subjects by Mr. Franklin L. Pope.

Messrs. King, Mendham, and Co.—On Saturday last the *employés* of this firm had their annual outing at Ilfracombe. The weather was most favourable, and a very enjoyable day was spent.

Aberdeen.—The Secretary for Scotland has formally sanctioned the raising by the Town Council of a loan of £20,000 for the execution of works under the Aberdeen Electric Lighting Order (1890). The Gas Committee have resolved to consult Prof. Kennedy as to the propriety of embracing the present opportunity of laying the iron tubes which would be required for street lighting, and the probable cost.

Belfast.—The Gas Committee reported at the last meeting of the City Council that they had advertised for offers of sites suitable for the erection of the electric lighting station. The replies had been referred to Prof. Kennedy for his opinion as to their suitability, and a sub-committee had been appointed to inquire and report upon those selected by him and as to the rentals thereof.

Bradford.—The Electricity Committee of the Bradford Corporation are at present considering the means of increasing their electric supply, in order to meet the growing demand for the light. They have had presented to them reports on the subject by Mr. Baynes, their own engineer, and Mr. Shoolbred, their consulting electrical engineer. Mr. Baynes points out that the three-wire system might be advantageously applied to the district in question. Mr. Shoolbred explains that he would follow the Continental practice where the five-wire and the three-wire arrangements, or, in other words, the converters, do not begin or come into operation except at the delivery end of the ordinary two-wire feeding mains.

Brighton.—The Town Council have approved the recommendation of the School of Science and Art Committee, that the school building be lighted by electricity; the work to be completed by the end of August.

Cape Town.—The Public Library at Cape Town is now lit by the electric light, and, in consequence, it will be open in the evening.

Cardiff.—On Monday the Mayor, Mr. W. E. Vaughan, J.P., laid the memorial stone of the new central station.

Dundee.—The gas fittings and standards for St. David's Church requiring renewal, it has been decided before proceeding with the work to obtain estimates as to the cost of introducing the electric light into the church.

Eastleigh (Hants.).—The Local Board have referred to their surveyor the question of the electric lighting of their new offices.

Glasgow.—At the meeting of the Town Council on Tuesday Mr. W. F. Anderson called attention to the proposed extension of the electric lighting machinery, but said he could not find that additional mains had been ordered. The Lord Provost said that the machinery originally provided was in connection with a totally different subject. It referred to the domestic lighting, which was greatly extending, and the mains in the streets were large enough to carry three times the power they had at present.

Grimsby.—It has been decided that the Public Lighting Committee shall consider the question of lighting the town by electricity, and the Borough Surveyor has been instructed to prepare estimates.

Japan.—The electric lighting of the towns of Japan is making considerable progress. Central stations at Hamamatsu, Maibashi, and Nikko have just been opened, the current in each case being generated by 2,000 volt alternating-current dynamos, and the power is supplied by Pelton water wheels. Everything connected with these installations is made in Japan.

Leeds.—The Leeds Corporation have agreed to contribute a portion of the expenses of placing before the Joint Committee of Lords and Commons evidence on the electric power protection clauses in the interests of municipal corporations.

Leicester.—A meeting of the Ratepayers' Protection Association was held on Tuesday, when a resolution in opposition to the proposed electric lighting scheme of the Corporation was carried.

London Central Markets.—The Court of Common Council on Friday adopted a report of the Central Markets Committee, recommending the acceptance of an agreement with the City of London Electric Lighting Company (Limited) for supplying electric lamps above the footways outside the markets, and for lighting and maintaining the same at an inclusive charge per annum of £598.

Madrid.—The tramway companies in Madrid have before them a scheme for changing the motive power from horses to electricity. The capital required is £400,000, which would be raised in Germany. It is proposed to work the trains for 25 years at a charge of 3½d. per kilowatt, the cars and electric plant at the end of this period to belong to the tramway companies.

Manchester.—The electric lighting department of the Corporation's Gas Committee have prepared a report for the year ended March 31st for presentation to the Council, in which they state that the station at Dickinson-street is almost complete, and they anticipate that current will be ready for consumers by August 1st.

Morley (Yorks.).—The Town Hall Committee of the Morley Corporation have decided to light the new Town Hall by electricity. It will also recommend the Corporation to appoint a special committee to report as to the advisability of obtaining powers to supply electricity for street lighting and for private consumption.

Newport (Mon.).—The Sub-Committee of the Parliamentary Committee on electric lighting has reported in favour of the adoption of the high-tension alternate-current transformer system as being generally the most suitable, and recommended the appointment of an electrical engineer to prepare plans, specifications, and estimates.

St. Pancras Vestry.—Mr. G. M. Clements, a member, has issued a memorandum containing statements in reference to the Stanhope-street central station, which Mr. Eccleston Gibb (the Vestry Clerk) characterises as "misrepresentations of the facts." After some discussion at the last meeting of the Vestry it was decided to defer the reception of the report of the Electricity and Dusting Committee until an answer had been prepared to Mr. Clements's memorandum by Mr. Gibb and Prof. Robinson. The residents and occupiers of Regent's Park-road having asked for the light, the Electricity Committee recommended that Prof. Robinson should be instructed to prepare specifications of the work, and that the Vestry should invite tenders. The estimated cost of the works was stated to be £2,650. The same Mr. Clements said there was every probability of the work costing £1,000 more than estimated, and that if they earned £602, after paying £522 for expenses and depreciation there would only be a miserable profit of £82.

Stafford.—The Corporation have decided, on the recommendation of the Electric Lighting Committee, to retain the services of Dr. John Hopkinson as electrical expert to report upon the electric lighting of the town, at an inclusive fee of 100 guineas. The Council have also decided to fit up electric bells at the house of

Digitized by Google

each member of the fire brigade, and to connect the police office and fire station by telephone.

SUTTON (SURREY).—The Local Board have retained Mr. Ed. C. de Segundo to report upon the electric lighting scheme for Sutton, and to advise them generally.

TORQUAY.—At Tuesday's meeting of the Town Council the Electric Lighting Committee reported that Mr. W. H. Trentham had been consulted by them respecting a site for a central electric light station. Out of the eight alternative sites inspected he recommended the Bath Saloon site as the most preferable. The estimated initial outlay was £17,403, and the annual cost of maintenance £3,100; and the revenue (it was anticipated) would be, without including that from meters, motors, cooking apparatus, &c., £3,320 at 6d. per unit. The Committee recommended that the matter be proceeded with on the basis of Mr. Trentham's report, and that plans, drawings, and specifications be prepared, and that the Local Government Board be applied to for sanction to borrow £18,000, which would include the cost of obtaining a Provisional Order. The Mayor, as Chairman of the Committee, said that important information had been received since this report was drawn up, and having regard to the importance of the subject he suggested, that the matter be referred back to the Committee for further consideration—a course which was adopted.

TUNBRIDGE WELLS.—The Tunbridge Wells Ratepayers' Association last week held a meeting at the Town Hall to again consider the electric lighting scheme proposed by the Corporation, and after some discussion a resolution was carried that it was advisable that the electric lighting should be kept in the hands of the local authority, instead of the Provisional Order being handed over to a company. The Town Council, at their meeting on Wednesday, were to consider a recommendation from the Electric Lighting Committee to establish electric light works, to supply electricity for both public and private purposes, at an initial cost of £13,000.

WORCESTER.—A special meeting of the Watch Committee was held last week to consider the tenders for the electric light works for the city. A number of tenders were received; but the amounts were greater than were anticipated by the Committee. It was, therefore, resolved not to recommend the acceptance of any tender, but to make further investigations and report to a subsequent meeting.

BOOKS RECEIVED.

"Transactions of the North-East Coast Institution of Engineers and Shipbuilders." Vol. IX. Parts 6 and 7. (London: Andrew Reid and Sons.)

"Annual Catalogue of the Massachusetts Institute of Technology, 1892-93." (Boston, Mass.: H. G. Collins.)

"The Atlantic Ferry." By Arthur J. Macginnis. (London: Whittaker and Co.)

THE TRAMWAYS INSTITUTE.

The annual dinner of the Tramways Institute of Great Britain and Ireland took place at the Holborn Restaurant on the evening of the 29th ult. Mr. W. J. Carruthers-Wain, the President of the Institute, in the chair.

The CHAIRMAN, in responding to the toast of "Success to the Tramways Institute," said that the question of electric locomotion had been largely considered at the Institute's meeting that day, and they were indebted to the various readers of Papers on the subject of electric traction and electric lighting of tramcars and omnibuses.

Mr. EBBSMITH, in proposing the toast of "The Traction of the Future," said that they had the representatives of various kinds of traction with them that evening, but electricity was exceedingly largely and well represented. They had votaries of all systems of electric locomotion, viz., the conduit system, the overhead-wire system, and the accumulator system, and in regard to them all he said that each was the best "under certain conditions." He coupled with the toast the names of Messrs. Etlinger and Epstein.

Mr. ETLINGER said that in his opinion electricity was too costly, and the "old gees" had it still. If the cost of production of electricity were reduced—say, for instance, a man had water-power at his command—then it might pay; but under existing circumstances, and in face of all he had read, he was not disposed to support or advocate it, but preferred to stick to the horses.

Mr. EPSTEIN advocated at some length the driving of cars by the accumulator system, and recapitulated the figures of a Paper he had prepared in regard to the actual working of tramways by the accumulator system, from which it appeared that the Birmingham Central Tramways Company had had their line fitted with 12 sets of accumulators, which represented 12,000 cells and 10,000 plates, and up to the present moment they had done their work, to the best of his knowledge and belief, on the Birmingham Central Tramway Company's line without the least hitch, and with no necessity for repairs to a single plate out of 10,000. The service was a five-minute one, and the gradients were very steep. They had at first some difficulty, owing to the severe weather at the end of December and in January and February, which caused, according to tests, an expenditure, through the snow and frost, of power equal to 33 I.H.P. He contrasted the various systems of electric traction, and maintained that a line could be equipped and worked cheapest by the accumulator system. He had, he said, paid a recent visit to the United States, and studied the systems of electric traction there, where the ideas of the people on the subject were certainly more advanced than ours. He was of the opinion that the accumulator system was a very good one for companies that had a varying traffic, as they could have just the number of cars they wanted running, and not have to keep, as in the case of steam, extra engines with steam up in the sheds. The charges that the Company he represented fixed with the Birmingham Central Company were originally lower than they were now recognised; it be understood that the maximum that was to be taken from the accumulators was 130 amperes, but it was found on careful tests during running that as much as 170 amperes were taken, and accordingly a current of 210 amperes was afterwards supplied, and an increase of 50 per cent. on the original charge agreed to. He promised to prepare for the use of the Tramways Institute a series of estimates of the cost for the conversion of lines of varying lengths from horse or other traction to accumulator traction. He expressed the opinion that accumulators were undoubtedly "the traction of the future." Overhead wires and underground wires were, he said, a mistake, being too much above or too much below us; but accumulators were a happy middle course. He had practical experience as well as theoretical knowledge, or he would not dare make these assertions.

COMPANIES' MEETINGS AND REPORTS.

United River Plate Telephone Company (Limited).

The seventh annual ordinary general meeting of the Company was held at Winchester House, Old Broad-street, on Tuesday last, "for the purpose of receiving and adopting the report of the Directors and the accounts for the year ending March 31, 1893; and for transacting the ordinary business of the Company." Mr. J. Irving Courtenay presided.

The SECRETARY (Mr. Robert Herring) having read the notice convening the meeting,

The CHAIRMAN said: Before moving the adoption of the report and accounts I propose to make some observations and explanations on the various paragraphs and figures they contain, though it is not necessary that I should do so at the same length as on former occasions. Last year I expressed an opinion to the effect that we had seen the worst of the trouble in the Argentine Republic, and I consider that the course of events in the interval that has elapsed has confirmed that view. There have been from time to time periods of depression and of uncertainty, times when the outlook had a gloomy aspect, but the net results have been decidedly to the good, and my hope is that such will be the outcome of the future. At the moment we note an unsatisfactory feature in the rise in the gold premium. Similar fluctuations have previously taken place, but the average of the year under review was 215 premium as contrasted with an average premium of 280 the year before, and we can but trust, in spite of present appearances, for a further reduction during the current year. A perusal of the figures given in the latest official report from the British Legation in the River Plate, in which attention is called to "the enormous strides made by agriculture in the Argentine Republic during the last year," cannot fail to create confidence in the ultimate rehabilitation of the financial credit of the Republic, as well as in a comparatively speedy return of its commercial and business prosperity, provided only there be a fairly intelligent administration of the national affairs. I will now, according to my custom, take you through the figures of the balance-sheet. The receipts of the Company have increased from £98,699. 8s. at par of exchange, the amount received during the previous year, to £115,542, or nearly £17,060 increase. This is the net amount after providing for any bad payers on the list of subscribers, though these now constitute a very small proportion of our list. The expenses, you will observe, are slightly smaller; but this figure may be expected to somewhat increase, as the expenses are now at a minimum, and with the business growing as it is there will be an increase in working expenses. I am glad to say that there has been an increase in the number of subscribers of 710, against a loss the year before of 125. The working for the year actually shows a profit of a little over £7,000, but the policy of the Board is to consolidate and strengthen the position of the Company, and to that end we have dealt with this sum in a manner that I trust will meet with the approval of the shareholders. We have written off the balance of the taxes suspense account, £768. This is the balance of an item which was spread over several years, and now disappears. We have also written off for bad and doubtful debts £2,728. This amount does not arise out of the operations of the year under review, but is a balance in connection with previous sales business of the Company in the various provinces. We have transferred £3,000 to depreciation and renewal fund, leaving this amount, in accordance with our Articles

Digitized by Google

f Association, in a form where it can be dealt with in the future s may seem most desirable; and there still remains a balance for the ar of £540 to be carried forward. The shareholders will have observed at notwithstanding the fall in the gold premium the loss on exchange is eater than it was in the previous year. The explanation of this is, that the net receipts in the Plate at par of exchange were nearly 50 per cent. ore, the loss in conversion, notwithstanding the lower gold premium, was nsiderably larger. I would point out that the loan from the bankers, 2,100, which appeared in the last balance-sheet, has been paid off. We ve reduced the amount that stood in previous balance-sheets £29,209, e cost of converting the Seven per Cent. Debentures and issue of benture stock, by the sum of £9,000, which amount was transrred from depreciation and renewal account for that purpose. I ay mention that we have just paid off the balance of the Seven r Cent. Debentures—that is, those held by the debenture holders ho declined to convert into Five per Cent. Debenture Stock. The ffect of these appropriations is to materially strengthen the Company's eneral position, and, of course, to improve the value of the Five per Cent. ebenture Stock in which so many of our shareholders are interested. An important change has been made in the administration of the Comany's affairs in the River Plate during the past year. Mr. Chappell, who was manager at Rosario, has been made the General Manager in the River Plate, while the Company retains the valuable services of Messrs. Fells and Krabbe, our former Managers, as Consulting Directors. By this arrangement we have effected a considerable economy, and we consider that it has been generally beneficial to the Company. We are very much indebted to all of these gentlemen and to the other members of the staff in Buenos Ayres for the care and attention they have given to the Company's business, to which the efficient service to our subscribers is due. One of our Consulting Directors, Mr. Krabbe, is here, and will be happy to answer any questions. Before concluding, I desire to allude to the paragraph in he Directors' report, in which they express their regret at losing Mr. Irwin from the Board, in which expression of regret I feel the shareholders will cordially join. I beg to move—

"*That the report and accounts submitted to the meeting be, and they are hereby received and adopted by the Company.*"

I will now call upon the Manager Director, Mr. Jones, to second the resolution.

Mr. FRANK W. JONES briefly expressed his pleasure at seconding the motion.

The CHAIRMAN: We shall be very pleased to answer any questions or give any further information in our power. After a pause he said: If no questions are put I will ask Mr. Krabbe, who has just returned from the Plate, and who we are very glad to see among us, to say a few words to the shareholders. I am sure that that will meet with your views.

Mr. KRABBE: I am, of course, more accustomed to take a local view of the work of the Company as regards Buenos Ayres than the ultimate result in England. We do our best to send home as much money as possible, and therefore the figures I more generally carry in my head are those absolutely belonging to the Plate. I am very pleased to come before you to-day instead of when the premium was at 350. Comparing in dollars our profit for the year with that of last year, it is $290.000 against $202,000, or, as our Chairman said, nearly 50 per cent. increase. This, of course, arises from two causes, from the subscribers on the one hand and the expenses on the other. There is a third cause which militates on the sterling result, namely, the premium, which is absolutely beyond our control. Our subscribers, I think, show a satisfactory and promising condition. They have increased considerably during the last 12 months, and, without wishing to prophesy, I think we can look forward to their being over 4,000 in Buenos Ayres alone within a short period. Of course, our object is to increase them as much as possible, and there are two causes which tend to an increase. One is naturally beyond our control, and that is the general condition of business out there, but certainly business has improved, apart from all political or gold questions, in the Plate in the last two years, and the condition of the country generally promises to allow a still further improvement. The other point in connection with the subscribers is, naturally, the service; and without wishing to take any praise to ourselves out there I can certainly say that we compare with regard to service very creditable with any other city, and certainly alongside of service that I have experienced lately. We, as a rule, give a prompt and efficient service, giving communication very much more rapidly than they do on this side of the water. Until there is an equilibrium between gold and paper prices out there—that is to say, the value of a sovereign and the value of a man's labour—it would be very difficult for us to economise in dollars any further. To put it more practically, I may say that there are men and women in our employ now who get, say, $40 a month. When gold was low we were paying them $30—that is to say, their wages have only increased 33 per cent., while the premium, as you know, has gone up to 250 points, and more than that. If the premium goes down, if gold becomes cheaper in Buenos Ayres, the wages in paper will not increase, but if the premium rises, it is only natural that wages will rise too. I am very much obliged to the Chairman for the kind way he spoke of us just now. I will only say that I think Mr. Fels, Mr. Chappell, and Mr. Parker, who has been manager at Buenos Ayres for many years, as well as myself, have your interests thoroughly at heart.

The CHAIRMAN then put the resolution to the meeting in the usual way, and it was carried unanimously. He afterwards proposed the re-election of Mr. Frank W. Jones as a Director of the Company. Mr. Jones he added, was the Managing Director, and was constantly with them.

Mr. C. L. W. FITZGERALD seconded the resolution, which was unanimously adopted.

On the motion of the CHAIRMAN, seconded by Mr. J. C. J. DRUCKER, Mr. Frederick Green was also re-elected to his seat at the Board.

Mr. FITZGERALD then proposed, and Mr. J. D. BONNER seconded, the re-election of the auditors, Messrs. Cooper Bros. and Co., at a fee of 25 guineas, and the motion was carried unanimously.

The CHAIRMAN: That concludes the business of the meeting. I think I shall be only expressing the wish of the meeting if I thank Mr. Krabbe for his information, and for the encouraging address he made to us in regard to the affairs of this Company and the affairs of the River Plate, in which we are also deeply interested. We all know that he and all the other members of the staff have had, and that they will continue to have, the interests of the Company at heart.

Mr. DRUCKER afterwards proposed a cordial vote of thanks to the Chairman and Directors for their able administration of the Company's affairs in the very unfavourable times which had been experienced.

Mr. FITZGERALD seconded the motion, which was carried unanimously.

The CHAIRMAN: On behalf of the Directors and myself I thank you very much. We are doing our very best for you. As regards anything in which we have control I believe there is very little fault to be found. We do our best according to our judgment. There are certain matters in which we have no control, and that fact causes us great anxiety, but it is impossible to go through our figures calmly without seeing what progress we have made. The gold question overhangs everything, but if that matter is placed on a satisfactory basis in the future and there is a stable Government, I have no doubt about the future of this Company.

The proceedings then terminated.

Electric Construction Corporation (Limited).

A meeting of the holders of the First Mortgage Debentures of the above-named Company was held on Wednesday, at Worcester House, Walbrook, E.C., Mr. R. E. Beachcroft presiding.

The SECRETARY (Mr. James Gray) having read the notice convening the meeting,

The CHAIRMAN moved the following resolutions:—

"*This meeting hereby sanctions the scheme for the reconstruction of the Electric Construction Corporation (Limited), set forth in the draft Resolutions produced to the meeting, so far as the same affects the holders of the First Mortgage Debentures of the Corporation.*"

"*This meeting approves the forms of the First Mortgage Debentures of the new Company and the Trust Deed to secure the same, which have also been produced to the meeting, and sanctions the exchange of the First Mortgage Debentures of the Corporation for First Mortgage Debentures of the new Company.*"

"*This meeting, pending the exchange of the First Mortgage Debentures of the Corporation for First Mortgage Debentures of the new Company, hereby suspends the right of the holders of the First Mortgage Debentures to take or prosecute against the Corporation any legal proceedings relating to the Debentures.*"

Sir HENRY MANCE, C.I.E., seconded the resolutions, which were carried with one dissentient.

A meeting of the holders of the Second Mortgage Debentures was held on the same day, Mr. E. Garcke (the Managing Director of the Corporation) in the chair.

The CHAIRMAN, in moving a series of resolutions similar to the foregoing, but applicable to the Second Mortgage Debentures, said that the holders had, no doubt, read the circular which accompanied the letter which the Directors had issued to the shareholders of the Corporation, and which set out fully the scheme of re-construction and the position of the debenture-holders. As regarded the First Mortgage Debentures, no change was proposed. With respect to the Income Bonds, it was suggested that they should accept £2 fully-paid Ordinary shares of the new Company of the value of £2 each in exchange for each £10 Income Bond. He thought, on the whole, that they would recognise that there were many advantages in effecting this exchange. The holders would rank with the Ordinary shareholders for dividend, instead of as at present waiting until the debentures to which the Income Bonds were attached had been redeemed. He might say that the Electric and General Investment Company, who were the trustees for this issue, approved the scheme so far as it affected the Second Mortgage Debenture holders, and recommend its adoption. He might also say that a meeting of the holders of the First Mortgage Debentures was held that morning, at which similar resolutions were all but unanimously agreed to, there having been only one dissentient. In regard to the Income Bonds, it would be necessary that they would be asked to sign a declaration of adhesion to the scheme. In regard to the Second Mortgage Bonds, that would have to be decided at once. In answer to Mr. Barclay he added that the trustees who represented them now would also do so in the new company and their security relatively to the first debenture holders, and to the shareholders would remain precisely the same as it was before, and the bonds would be redeemed by drawings half-yearly as at present. The first of these drawings had already taken place, £2,000 having been paid off, so that the total issue was £98,000 instead of £100,000. In answer to a shareholder, he said that the bonds issued last December amounted to £50,000. It would be remembered that the Board then wisely allotted the whole of the issue to the shareholders rateably, and only such bonds as were not taken up by the shareholders were issued to outsiders, and in this way £50,000 was subscribed. The balance of £50,000 remained in the hands of the Company, and had since been issued. They were not asking the shareholders to make any sacrifice. The capital was now being reduced from £10 to £4 shares, and the Income Bonds were reduced in the same proportion. Consequently, they were not making any sacrifice, but on the contrary, they were being benefited. This reconstruction scheme would mean an improved credit for the Company, and enable them to do

Digitized by Google

better business than they were now able to do, and their security would be enhanced in value in public estimation.

Mr. BLANDY seconded the resolutions, which were carried unanimously.

An extraordinary general meeting of the Company was subsequently held at the Cannon-street Hotel, the Chairman (Sir Daniel Cooper, Bart., G.C.M.G.) presiding.

The notice convening the meeting having been read,

The CHAIRMAN said: Gentlemen, I explained to you on the occasion of the last general meeting that the Board was in course of being reconstituted. It was suggested by some of the shareholders that a Committee of Investigation should be appointed, and I promised you that the Directors themselves would investigate the whole of the affairs of the Company. Well, the Board has been reconstituted, as we have mentioned in the report which is in your hands. During the past year seven Directors have retired from the Board, and the three new Directors, Mr. Plunket, Mr. Barclay, and Mr. Garcke have been appointed. You will see, therefore, that we are now practically a new Board, and I can assure you that if you had seen how difficult it was for some of us to get control of the business under the old *régime* you would be able to appreciate the full force of what this reconstitution of the Board means. Some of us have been Directors of the Corporation since the commencement, but, as you are aware, the Board was at one time a very large one, consisting of about twelve members, and it was divided into Committees, so that those of us who were not on the Committees were frequently kept in the dark as to what was being done until the steps taken had become irrevocable. I cannot tell you how very grateful I feel for the changes that have been made. These changes have relieved me from a very unenviable position, and I feel much indebted to the members of the present Board for the way in which they have supported me. It has been a very difficult time for all of us, and if we had not stood well together the consequences to the Corporation might have been serious. My colleagues have worked very hard. I had occasion to mention at the last general meeting how my friend Mr. Courtenay had, during the difficult period of transition taken up the reins of management and had prepared the way for the Corporation making the important changes I have referred to. Since then he has been assisted by the new Directors, and they have attended at the office from day to day, and have spent several hours there each day, examining into the affairs of the Corporation, and conferring with the Managing Director as to the reforms which have had to be carried out. One of the first steps we had to take after the last general meeting was to appoint a Managing Director, and the Board consider that they have been fortunate in securing the services of Mr. Garcke, who has had a large and wide experience in the electrical business. It then became necessary to appoint a new secretary, a new accountant, and to make several other changes in the staff, and I am glad to be able to tell you that these changes have already produced very good results. One of the first things that had to be done was to cut down the very heavy standing charges, and the Managing Director, who will address you, will tell you what has been done in the direction of effecting economies. Then the financial position presented many difficulties, and it was only by the Directors coming forward and assisting the Corporation, and undertaking responsibilities for the Corporation, that we were able to meet our various engagements. I shall not regret what I have myself done in this respect if you enable me to feel that we have your support and appreciation. The result of our investigation is that a thorough reorganisation of the business and a reconstruction of the Company is absolutely necessary. It is needless for me, as one of the largest shareholders in the Corporation, to say that I regret the necessity for doing this. I am one of the largest sufferers, and therefore I am able to sympathise with you; and the view that we hope you, as men of business, will take is that it is our bounden duty to remain at our posts and to save what remains, and endeavour to recover what has been lost. The Board are convinced that the best way to carry out the reorganisation is by means of the scheme of reconstruction now before you, and by the formation of a new Company. At present the credit of the Company is prejudiced by the shares being of a large discount, and this makes it very difficult for our managers to get contracts and to carry on the business economically. The position of the Company is by no means what the price of the shares indicate, and I am expressing the views of my colleagues, as well as of myself, when I state that it is our belief that, with the careful management and energy with which we intend to push the business, there is a prosperous future before the new Company. The important contracts which have been entrusted to us, and which we have carried out successfully, by the aid of our Works Director (Mr. Parker) has laid the foundation of profitable work in future. I think it right to tell you that, acting under the advice of the solicitors, I have, as one of the largest shareholders and creditors, filed a petition for winding-up, in order to prevent what are generally known as wrecking petitions. When that petition comes on for hearing I propose to ask the Court to make an order to continue the voluntary winding-up under the supervision of the Court. I now propose the first special resolution, of which you have had notice:—

"*That it is desirable that the Corporation be reconstructed, and that with a view to such reconstruction the Corporation be wound up voluntarily.*"

I will not trouble you with the other resolutions at this stage. I take it we can discuss the position generally upon the first resolution, and if the principle embodied in that resolution is adopted by you, the rest of the resolutions will be put to the vote, and, I hope, carried as a matter of form. I call upon Mr. Garcke, our new Managing Director, to second the resolution.

Mr. E. GARCKE, in seconding the resolution, delivered a long address, setting forth the circumstances under which the new Board entered on their work a few months ago. He said that while the Board were bound to recognise that there had been mismanagement in the past they were satisfied that with strict economy and prudent management in the future there was no reason whatever why they should not retrieve the errors of the past and occupy a leading position, and in many respects the leading position in the electrical industry. Many of their investments were of such a character that if properly developed and taken care of promised not only to become valuable and realisable in cash, but would, he hoped, have the effect of largely increasing the business of the Corporation. He then elaborately explained the scheme of reconstruction, the terms of which were fully set out in *The Electrician* last week.

The Right Hon. D. PLUNKET, Q.C., M.P., also expressed his confidence in the ultimate success of the Company if the scheme of re-construction were carried into effect. The Directors had satisfied themselves that there was a *bonâ fide* valuable property to be worked which had come to grief through mismanagement in the past; but with the re-constituted board, hard work and rigid economy, and straightforward dealing, they would succeed in putting the company on its feet again.

Mr. BEACHCROFT also spoke in support of the scheme, into the details of which he had gone most carefully, without being able to find a single objection to it.

Mr. HANCOCK animadverted on the past management of the Company, after which the resolution was carried unanimously.

All the other formal resolutions giving effect to the reconstruction were afterwards agreed to *nem. con.*

Mr. JAMES W. BARCLAY proposed a vote of thanks to the Chairman, not only for his conduct in the chair, but for the invaluable assistance which he had given to the Company in the difficulties in which it had been placed, not only by his able counsel, but by the money he had put into the concern. He was sure that if they had not been backed up by Sir Daniel the results would have been disastrous.

The Right Hon. D. PLUNKET seconded the motion, which was cordially carried.

The CHAIRMAN having expressed his acknowledgement of the vote, the proceedings ended.

Eastern Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended March 31st last, to be presented to the forty-second half-yearly Ordinary General Meeting, to be held at Winchester House, E.C., on Thursday, the 13th inst., at one o'clock:—

The revenue for the period amounted to £372,852. 10s., from which are deducted £102,499. 7s. for the ordinary expenses, and £32,532. 17s. 11d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £5.263. 18s. 8d. for income-tax, there remains a balance of £234,556. 6s. 5d., to which is added £62,942. 4s. 4d., brought from the preceding half-year, making a total available balance of £297,498. 10s. 9d. From this balance there have been paid:—

Interest on debentures and debenture stock	£27,891	0	3
Dividend on Preference shares	20,474	1	8
An interim dividend of 2s. 6d. per share on the Ordinary shares	50,000	0	0
	£98.365	1	11

Leaving a balance of £199,133. 8s. 10d., from which £88,000 has been carried to the general reserve fund.

The Directors now recommend the declaration of a final dividend for the year ended March 31, 1893, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 13th inst., free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year, on the Ordinary shares. The balance of £1,133. 8s. 10d., shown at the foot of the revenue account, is proposed to be carried forward to the next half-year.

The revenue includes £20,991. 12s. dividends and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

Since the last general meeting the Eastern and South African Telegraph Company, under an arrangement with this Company, has entered into an agreement with Her Majesty's Government to connect the Islands of Seychelles and Mauritius with Zanzibar and this Company's general system of cables, in consideration of subsidies amounting to £28,000 per annum for a period of 20 years. To carry out this work the Directors of this Company issued, for account of the South African Telegraph Company, £200,000 Four per Cent. Registered Mortgage Debentures, part of a total authorised issue of £300,000 like Debentures secured upon these subsidies. The subscriptions were largely in excess of the amount offered.

Negotiations have for some time been in progress with the Portuguese Government for connecting the Islands of the Azores with Lisbon and this Company's general system, resulting in an agreement with that Government for the carrying out of this work. A Company is being formed to lay this cable and work it under the conditions of the contract with the Government. It is expected the cable will be laid in August next.

The Directors regret to report the death on May 7th last of their valued and esteemed colleague, Sir James Anderson, Managing Director of the Company since its formation. The vacancy has been filled up by the appointment of Mr. J. Denison Pender, who has been a member of the Board for many years. Mr. C. W. Stronge, C.B., for several years an Official Director, appointed by H.M. Treasury, has, on retiring from that office, been elected an ordinary Director of the Company.

Digitized by Google

India-Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The half-yearly general meeting of this Company was held at the Cannon-street Hotel on Wednesday (Mr. S. William Silver in the chair), "for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax."

The SECRETARY (Mr. William J. Tyler) having read the notice calling the meeting.

The CHAIRMAN said: That is really the object of our meeting to-day, and we are very glad to see you. You may remember, perhaps, on the last occasion that I referred to a cable that we had just manufactured, between 2,000 and 3,000 miles long, which we were then about to lay in the Pacific. That work has been completed and paid for, and I believe I am justified in saying that it was one of the best cables we have made. With respect to the trade generally, I am very glad to say that the returns are equal to those of previous years—indeed, somewhat in excess. I do not know that I can add to these remarks, but I will ask my friend, the Managing Director, to give you afterwards a report of the French works which he has just paid a personal visit to. I will now conclude by moving that a dividend of 5 per cent., or 10s. per share, free of income-tax, payable on the 6th inst., be now declared.

Mr. ABRAHAM SCOTT: I beg to second the resolution.

The motion was carried unanimously.

The MANAGING DIRECTOR (Mr. Matthew Gray): As the Chairman has just said, I have been within the last few weeks visiting our French works, and I am glad to inform you that everything is going on there satisfactorily. We have very nice little works there, and they are doing very good work, and, I believe, they are doing it on a proper basis, which will give a moderate return for our exertions. I do not think the shareholders need be at all anxious about the French works. I think they are in a very good condition, and they are likely to be satisfactorily managed. I do not know that I have anything else to say as far as the French works are concerned. I regret to tell you that one of our agents, our agent for Ireland, who had been with us for 19 years, and who was a very worthy man, died about three weeks ago of heart disease. I went over to Ireland 0 days ago for the purpose of making arrangements for carrying on our usiness there, and I have just returned, having made, I think, arrangements which will prove satisfactory. Although I express my very sincere egret at the death of our old and worthy agent, still I think it will not turn out so injurious to us as one might have expected, as I think the arrangements now made are such as will enable us to carry on our Irish business in as satisfactory a manner as hitherto. The works at Silvertown are in first-rate condition, and everything is going on in the usual manner, and, I think, satisfactorily. We could do some more cable work, I believe, if we had it to do, but, as you all know, submarine cable work comes in fits and starts. We do the best we can when we get orders, and we must "grin and bear it" when we do not get them.

The CHAIRMAN: That concludes our business, gentlemen, and I thank you for your attendance.

Mr. MARTINDALE said that before the meeting separated he desired to have the privilege of proposing a vote of thanks to the Chairman and Directors. He regarded their dividends as very satisfactory and considered that the thanks of the shareholders were eminently due to those who managed the affairs of the Company in such an efficient manner.

Mr. TREBLE seconded the motion, which was unanimously agreed to.

The CHAIRMAN: We thank you, gentlemen, for this fresh proof of your confidence.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

BINDLEYS (LIMITED).—This Company, which was registered on June 2, 1893, with a capital of £6,000, in £10 shares, for the acquisition of an ironmonger's business at Burton-on-Trent, Staffs., includes among its objects the manufacture and sale of electric, magnetic, telegraphic, telephonic and other apparatus and appliances.

LAMINA ACCUMULATOR (ELIESON'S BRITISH PATENTS) SYNDICATE (LIMITED).—This Company was registered on June 29th with a capital of £2,000, in £1 shares, to enter into and make binding on the Company an agreement to be made with C. P. Elieson for the acquisition of certain patents granted in the United Kingdom of Great Britain and Ireland for and relating to electric accumulators or storage batteries, to develop and turn to account such patents and inventions, to carry on the business of electric light, heat and motive-power supply company in all or any of its branches and in particular to construct, lay down, establish, fix, and carry out all cables, wires, lines, accumulators, lamps, and works necessary for the carrying on of the business of the Company. The subscribers, each one share each, are:—Earl of Galloway, 17, Upper Grosvenor-street, W.; Moritz Immisch, 119, Torriano-avenue, N.W.; A. J. Morison, 10, Mincheap, E.C.; M. Frederison, 8, Regent-street, W.; F. D. Schiattino, 8, Regent-street, W.; Lewis Goldspink, 5, Thornhill-crescent, N.; Alfred Phili, Albion House, Stainsby-road, E. The number of Directors is not to be less than three, nor more than five. The first are:—The Right Hon. the Earl of Galloway (Chairman), Alex. J. Morison, Moritz Immisch, Francisco A. Pellas, and C. P. Elieson.

T. L. HEMMING AND CO. (LIMITED).—The annual return of this Company, recently filed, shows that 421 shares of the nominal capital of £5,000, in £10 shares, have been taken up, of which 130 were issued as fully paid to Thomas L. Hemming, the vendor. Upon 271 shares the full amount has been called up on 10 shares £5 per share, and upon the remaining 10 shares £1 per share, resulting in the payment of £2,770.

WYNDHAM ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to March 3, 1893, and filed in April following, shows that out of a nominal capital of £1,500, in £1 shares, 885 have been taken up. Of these 250 were issued as fully paid, while a call of 15s. per share has been made on the remaining 635, resulting in the payment of £199. 15s., and leaving £276. 10s. in arrears.

CITY NOTES, &c.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—At the adjourned meeting of the shareholders last week it was announced that as a result of the conference between the sub-Committee and the Chairman (Mr. Jasper), the latter gentlemen undertook to sell to any shareholder any of the shares proposed to be allotted to him in consideration of the money he had spent in carrying on the works. A resolution allotting him the shares to the amount of £18,630 was thereupon carried.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 2nd were £811, as against £763 for the corresponding period of last year, being an increase of £48. The total receipts for the half-year amount to £22,610, against £20,895 in the corresponding period of 1892, being an increase of £1,715.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of June are £3,200, as compared with £3,420 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY.—The gross receipts for the month of June were £1,730, as compared with £1,966 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of June amounted to £62,564, and to £52,173, in the corresponding period of 1892 an increase of £10,391.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of the Eastern Extension, Australasia and China Telegraph Company (Limited) for the month of June, 1893, amounted to £45,443 and to £41,738 in the corresponding period of 1892; increase, £3,705.

ELMORES' FOREIGN AND COLONIAL COPPER DEPOSITING COMPANY (LIMITED).—There was a private meeting of this Company at Winchester House on Friday last.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for June amounted to £24,800, and from January 1st to June 30th to £132,800. In the corresponding months of 1891 and 1892 the amounts were £141,400 and £128,800 respectively.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED). At the extraordinary general meeting of this Company, held at Winchester House, E.C., on Monday last, the Directors were authorised to create £10,000 in Six per Cent. Second Debentures.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors recommend the following dividends, less income-tax, for the last half of the financial year, ended April 30, 1890, viz.:—At the rate of 6 per cent. on the amounts paid-up on the First and Second Preference shares; at the rate of 5 per cent. per annum on the amounts paid-up on the Third Preference shares; at the rate of 5 per cent. on the amounts paid-up on the Ordinary shares, making with the the interim dividend already paid, 5 per cent. for the year, leaving a balance of about £32,000. The transfer books of the Company will be closed from the 5th inst. until the 18th inst., both days inclusive.

ONCKEN'S PATENT STAVELESS BARREL COMPANY (LIMITED).—A private meeting of this Company was held on Monday at the Cannon-street Hotel. An attempt is to be made to obtain further capital.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—A meeting of the Debenture holders of this Company will be held at No. 251, Winchester-house, Old Broad-street, on Tuesday next, the 11th inst., at 2 p.m., for the purpose of (1) authorising the trustees under the said deed to assent to and, if considered advisable, concur in the grant of a lease by the Company of the property and premises comprised in the said deed; and (2) sanctioning a modification of the rights of the Debenture holders as regards the date and amount of the sinking fund payments provided for by the said deed.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company give notice of the drawing of 110 Five per Cent. Mortgage Debentures of £100 each. These debentures will be paid off at par on September 1st next, at the National Bank of Scotland (Limited), Nicholas-lane, Lombard-street, E.C., and interest will cease after that date.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 30, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,369.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED.)—The receipts for the two weeks ended June 30th were £2,292, as compared with £2,196 for the corresponding period of last year.

Digitized by Google

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY, LIMITED (LEEDS).—This Company invite subscriptions from the present shareholders of the Company for the remaining 2,634 shares of £5 each, which, if subscribed, will bring the capital of the Company up to £50,000 out of a total authorised capital of £100,000. The money is required (the prospectus states) for an extension of the works at Leeds. The Directors consider that the success already attained justifies them in regarding the Company's shares as a safe and profitable investment, and further state that they already hold more than one-fifth of the subscribed capital and propose to apply for no less than £3,000 of the present issue.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 791.—Vol. XXXI. FRIDAY, JULY 14, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The most noteworthy feature of the first number of the *Physical Review*, which lies before us, apart from the printing and paper, which being American, are of course good, is the space devoted to reviews and the manner in which that space is used. Hitherto, the American scientific reviewer has inculcated the monotonous text that all transatlantic geese are swans, and it is, therefore, refreshing to at last see judicious *critiques* by competent critics. Amongst the contributors to the inaugural number are Profs. Nichols and Sheldon and Messrs. Bedell and Crehore, the two last giving a neat geometrical proof of the three-ammeter methods of measuring power.

We publish this week an important article by Mr. Oliver Heaviside on the analogy between gravitational and electromagnetic action. Mr. Heaviside has based his analogy on the supposition that gravitational energy may be located in its medium of propagation in the same way that electromagnetic energy is located in the ether; and that the former, like the latter, propagation is an elastic displacement in a medium possessing a certain amount of inertia. With this assumption it is necessary, among other things, to reconcile the apparently infinite rate of propagation of gravitational force; and this has been done by the author in a very ingenious manner, namely, by the assumption of the extreme smallness of the magnitude of the constant μ, and the consequent negligibleness of the corresponding value of the term T. In order that c should be really infinite it would be necessary to make the constant μ indefinitely small; and this would introduce inconceivable consequences when we should attempt to evolve any physical conception of the process of gravitational action. But it is by no means necessary to assume that the value of c is infinite. If Laplace, in his calculations on solar gravitation, was unable to detect in the motions of the earth and other planets any variation which might indicate the existence of a finite "aberration constant" of gravitation, it by no means followed that such a constant of aberration was non-existent; for it might exist, and yet be too small to be measured either directly (as Laplace proposed) or indirectly by a series of astronomical observations extending over many hundreds of years. Thus, the absence of any detectable constant of aberration is no obstacle in the way of Mr. Heaviside's analogy. On the other hand, however, the qualities required in the ether which might be assumed to permit of such a minute aberration are more subtle than those of the comparatively gross ether with which electricians are supposed to be acquainted; and it is difficult to reconcile the simultaneous existence of both, unless, indeed, the grosser of the two be discontinuous.

Speaking of aberration in relation to gravity and to light, we may remark that the latter phenomenon is one of the most insurmountable obstacles to a complete ether theory. The slant which is given to the apparent direction of a ray of sunlight or starlight is due to the combined motion of the earth through space and the velocity of the light wave. This phenomenon seems to imply that the motion of the earth and of other matter through space does not drag the ether with it; whereas, some experiments by Fizeau and others on the passage of a light ray through a rotating glass cylinder seem to indicate the contrary. If any such aberration exists gravitationally, as it must if the velocity of gravitation is not infinite, the apparent centre of attraction of the sun must execute an elliptic path round its real centre, the amplitude of which will be in proportion to the slowness of the propagation of gravitating force. This eccentricity or wobbling of the centre of attraction would, of course, produce a definite and continual alteration of the earth's orbit and of the orbits of other planets. The consequences of as large an aberration as that of light would be appalling; but the consequences of a very minute aberration might, like that of the tidal evolution which has been discovered by Prof. George Darwin, be only measurable after millions of years.

The approximate method for measuring the strength of a magnetic field, which Mr. Russell suggests in this issue, may prove convenient in some cases. The apparatus needed is certainly of the simplest kind; but an ammeter is a necessary adjunct, and, although the instrument is now common enough in laboratories, it should be remembered that when an ammeter is available the simplest method of getting a fairly accurate value of H is to make use of an ordinary tangent galvanometer. This instrument, which is found in every laboratory, is usually employed to measure the strength of a current, the value of H being assumed. The process can, however, be reversed when a current of known value can be passed through the coils, since the instrument can then be used to determine the strength of the controlling field. The objection urged by Mr. Russell against the magnetometer method, that the magnetic needle must be small to secure good results, applies

Digitized by Google

with equal force to his own method, which has the further disadvantage that the wire conveying the current must be long compared with the distance of the magnetic needle. This fault is not present in the tangent galvanometer method. Mr. RUSSELL's plan may, however, be utilised in another way, and we suggest the following process for forming a rough estimate of the number of amperes flowing in a vertical wire. If a small compass needle be placed east or west of the wire at such a distance that the magnetic force due to the current exactly neutralises that of the earth, this distance, reckoned in centimetres, will be practically equal to the current in amperes.

UNTIL medical electricians discard the cacophonous and archaic terminology in which the majority of them at present indulge we are afraid medical electricity will find it difficult to succeed in freeing itself from the suspicion of quackery under which it at present labours. In a recent communication to the Académie des Sciences, for instance, M. D'ARSONVAL commences by telling us that in electrotherapeutics the three principal methods of treatment are *franklinisation*, *voltaisation*, and *faradisation*, to which he himself has added two new forms of torture yclept *sinusoidal voltaisation* and *high-frequency electrification*, and now proposes a third horror, to be called *auto-conduction*.

FOR the purposes of carrying out auto-conduction M. D'ARSONVAL employs a cylindrical framework of wood or glass around which he winds several turns of electric light cable. The patient is placed inside this cage, and an oscillatory discharge from a condenser is sent through the cable. The condenser, consisting of from two to twelve Leyden jars, 50cm. high by 20cm. in diameter, arranged in two groups "in cascade," is charged by a 15,000-volt transformer connected to a Siemens 60 ∿ alternator capable of giving 12 amperes and 350 volts.

M. D'ARSONVAL's method requires the reproduction of magnetic fields of identical intensity, and his way of doing this is ingenious. Inside a subsidiary coil connected in series with the main solenoid he places a mercury thermometer; the Foucault currents generated in it by the varying field raise the temperature, and the temperature, provided the frequency is constant, gives a measure of the field strength. With four Leyden jars in circuit, the thermometer runs up to more than 150°C. in a few seconds.

SATISFACTORY meters and satisfied consumers are, it would seem, as rare in Germany as elsewhere. In Cologne, indeed, the city authorities have found it necessary to reassure the discontented public mind by a pamphlet, pointing out that the complaints which have been rife among the consumers of municipal electricity that their bills are too high are due to the elementary fact that 80 watt 25 candle lamps have been fixed in lieu of the more humble and usual 16 c.p. lamp. Henceforth the municipality proposes itself to sell lamps for 8d., giving 16-19 Hefner candles and taking from 52 to 56 watts to start with, these figures being respectively 10-12 candles and 40-45 watts at the end of 800 hours. It is not surprising therefore, to learn that in Cologne, at any rate, the demand for current continues to increase, notwithstanding the growing favour of the Welsbach burner, that powerful competitor of the German glow lamp. The Cologne municipal station has at present the equivalent of 32,000 8 c.p. lamps connected to its mains.

SHOULD the large sums which the National Telephone Company are by all accounts lavishing on their London system fail to render telephonic communication in the metropolis all that it ought to be, it is satisfactory to know that a sure remedy lies ready to hand—we must all learn French. According to the Association Professionnelle des Sténographes Français, the result of two years' experience on the London-Paris telephone line is to demonstrate the telephonic inferiority of the English language, and the superiority of French. The consequence of our evil habit of accentuating one syllable, usually the first, of each word, is said to be that the accentuated syllable as often as not arrives all alone at the far end of the line. On the other hand, the French and democratic custom of placing all the syllables of a word on an absolute equality gives them all an equally good chance of getting through. The facts seem to favour this view of the matter, and the theory, of course, is—sound.

IT is stated that in accordance with a curious custom which obtains in France, 10frs. was paid to each shareholder attending a recent meeting of the Société Générale des Téléphones. New telephone companies do not seem to thrive on English soil, but should such a one ever be started again, the prospect of a fee for attending the meetings might, perhaps, induce its shareholders to at least make a vigorous effort to maintain the concern in a position of freedom and independence.

AN inventor is one of those distinguished individuals who are born, not made. Some of us are so lacking in inventive instinct that even under extremest pressure we could not invent so much as a plausible excuse. Some, on the other hand, work out inventions in their dreams. No one, so far as we know, has as yet been bold enough to write a book on "How to Become a Poet," yet variations on the title "How to Become an Inventor" are as plentiful as variations on "Home, Sweet Home." To take to poetry as a profession would be deemed ridiculous; yet to take to inventing as a sole means of livelihood seems to some a most natural proceeding. What this leads to more often than not is exemplified by the fate of the late M. ARCHEREAU, whose death we recorded in our issue of February 24th last, and upon whose grave there was laid, a few days ago, the conventional "très belle couronne," subscribed for by the "Syndicat des Inventeurs de France" and others. ARCHEREAU died in poverty, yet during the siege of Paris he rendered a national service, which was scarcely adequately rewarded by a pension of 10d. per diem. The hospitals were sadly in want of fuel, and remembering that ARCHEREAU was the inventor of *briquettes* they

Digitized by Google

applied to him for assistance. Within a week he was turning out for them some 80 tons of coke *briquettes* a day. The moral would seem to be that all who prefer a comfortable competence on this side of the Styx to a "very beautiful crown" on the other should eschew works pretending to tell them "How to Become an Inventor," and strenuously cultivate the business faculty.

Interurban Telephony.—The telephone trunk line between Berlin and Königsberg, a distance of about 500 miles, has now been completed, and a section is in operation.

Dielectric Constants of Biaxial Crystals.—In a recent number of the *Comptes Rendus* there is an interesting account of the researches of M. Borel on this subject. The results of experiments on a large number of crystals are published.

Cable Interruptions.—

	Interrupted.
Paramaribo—Cayenne	April 15th.
St. Thome—Loanda	May 30th.

Lightning Conductors.—In spite of the fact that Rounton Grange, in Northumberland, was provided with three separate lightning conductors, the building was struck by lightning in the recent severe storm. Little damage was done except in the shattering of a portion of the masonry.

Austin (Texas).—The City of Austin (Texas) has in course of construction some large reservoirs for storing potable water. A power house is to be erected close to the main dam to contain eight 500 H.P. horizontal turbines driving dynamos intended to supply light and power to the city three miles off.

Kensington Vestry and Electric Lighting.—At a meeting of the Kensington Vestry, last week, Major-General C. E. Webber was appointed consulting electrical engineer to jointly report with the Vestry's lighting engineer as to the advisability of the Vestry applying for a Provisional Order for electric lighting purposes.

Owen's College, Manchester.—Bishop Berkeley Research Fellowships have been awarded by the Council as follows:—H. B. Pollard, M.A. (Oxon), in Zoology; Albert Griffiths, M.Sc. (Vict.), in Physics; J. A. Harker, D.Sc. (Tübingen), in Physics; Bevan Lean, B.A., B.Sc. (London), in Chemistry; and a Fellowship has been renewed to Stanley Dunkerley, M.Sc. (Vict.) in Engineering.

Telegraphy in Siam.—The interruptions in the Siamese telegraph service, says the *Indian Engineer*, have been so frequent and continuous of late that the principal firms of Bangkok met to discuss what steps should be taken to secure some improvement in the service. It was decided to petition the Foreign Minister with a view of remedying the grievance. The principal German traders also held a meeting in the German Club with the same object.

The Central London Railway.—In the City, at junctions of the various streets near the Mansion House, portions of the roadway close to the footpath have been boarded over and railed-in. These points mark the sizes and positions of the proposed approaches to the underground station. By arranging to have several entrances to this principal station, it will be provided that neither the passengers nor the public will be under the necessity of crossing the crowded roadways.

Colliery Accident.—A singular accident, arising from a faulty arrangement of electric signal wires in a coalpit, was described by the Manager of the National Colliery, Wattstown, at a recent meeting of colliery officials at Pontypridd. It seems that a fall of roof occurred at the in-take; and a quantity of the *débris* falling upon the signal wires, brought them into contact with each other. The heat generated at the contact ignited the coal dust which fell upon the wires, and an outbreak of fire occurred.

Gas and Electricity.—Some interesting facts and figures on "the present and future competition between gas and electricity" are to be found in a recent number of the *Gas World*. The information relates particularly to the United States. At the present time, out of 928 gas companies in the United States, only 435 have contracts for street lighting, and many of these are in competition with electric lighting. The arc lighting in the United States involves an annual consumption of 145,000,000 carbons.

Arc Lamp Fatality.—On the Piazza Quirinal at Rome two electric light lampmen recently lost their lives. One of the large lamps opposite the Palace suddenly went out. The lampman belonging to the district brought a ladder and ascended, but had scarcely touched the carbon when he fell to the ground from a height of some 16ft. His companion, believing him to be seized with sudden illness, went up in his place, but also immediately fell. Both men had neglected to use the switch short-circuiting the lamp. The men were both dead.

Telephonic Communication in the United States.—The following table shows the mileage of wire in use in the United States for telephonic communication at the commencement of each of the last twelve years:—

	Miles.		Miles.
1892.....	52,205	1888.....	202,617
1883.....	83,105	1889.....	243,764
1884.....	115,265	1890.....	279,941
1885.....	137,223	1891.....	331,642
1886.....	155,791	1892.....	381,554
1887.....	172,928	1893.....	421,027

Telephone Wayleaves.—The Highway Committee of the West Riding County Council have recommended that notice should be given terminating all existing agreements with the National Telephone Company, permitting the Company to erect poles on the main roads of the Riding, with a view to new agreements being entered into, containing, amongst other provisions, a reservation in favour of the County Council to carry not exceeding two private lines of wires for county purposes along all poles belonging to or under the control of the Company within the Riding.

Electrolytic Copper.—An immense electrolytic copper refinery has, says the *Engineering Magazine*, been started at Great Falls, Montana, by a Boston Company. It comprises 288 depositing vats, capable of containing at one time 710 tons of pig copper anodes, and has a capacity of 555 tons of pure electrolytic copper per month. The plant is run by water power, situated at a distance of about half-a-mile from the works. The current is supplied by two 165 kilowatt dynamos. The metal to be refined contains a large percentage of silver, all of which will be saved by the electrolytic process employed.

The Latest Form of Trolly.—According to the *Baltimore Sun* the novel sight of a man taking the place of the trolly-rod on an electric car was recently seen on the Lake Roland Elevated Railway. The trolly on one of the large electric cars was caught in a wire, and the entire trolly apparatus was torn off, falling to the street. The accident happened at a time when the traffic was heavy, and it was necessary to prevent a block. A linesman was equal to the occasion. He procured a piece of insulated wire, and after stripping each end of the insulating material, connected one end through the car roof and standing on the top of the car, held the other end against the wire. A connection being thus made the car was run over the elevated stucture to the car shed without accident or delay to the other cars.

Electric Traction in Naples.—As a rule we are somewhat chary of noticing projected schemes, but a railway concession recently obtained by Signor A. Avena certainly claims attention. It is proposed to bridge the lower part of the town by viaducts carried from hill to hill. The populous and beautiful part of the town which centres in the Via Roma is only connected with the Corso Vittorio Emmanuele, the hill of St. Martino and the Rione del Vomero by steep and narrow streets, many of which are impassable to carriages, and the proposed line is to be carried on two iron viaducts, each bearing one line of rails and a passenger way. The viaducts are to be carried on towers 300ft. or 400ft. high, so as to end at the Rione del Vomero on a level with the top of the hill. Lifts are, of course, to be provided.

The Inefficiency of the Sun as a Means of Illumination.—Prof. Blake, of the University of Kansas, in a lecture delivered in that town makes the following comparison between the light of the sun and of the electric light at the Chicago Exhibition. By Prof. Langley's experiments on Mount Whitney, the Professor states 1·6 kilowatt of energy per square metre of earth's surface is received from the sun when vertical, of this only 35 per cent. is light. The area of the Exhibition grounds is 1,037 acres, or 4,200,000 square metres. To light this space by the sun we should require 1,466,500,000 watts, or 1,965,000 H.P. In lighting the grounds by electricity, using 5,200 arc and 90,000 incandescent lamps, 14,200 H.P. are expended. So that if we like to overlook the difference in quality and quantity we may plume ourselves upon the fact that the sun expends about 145 times more energy to light the Exhibition grounds than man.

Electric Power for Factories.—At a recent meeting of the New England Cotton Manufacturers' Association a Paper was read describing some recent developments in electric power transmission and distribution. The author stated that multiphase synchronous motors were to be used in transmitting power from Sewall's Falls on the Merrimac River to Concord, N.H., a distance of some four miles. There is a total available power at this place of 5,000 H.P., and it is expected that about 3,500 H.P. will be transmitted and utilised. One of the most valuable applications of the electric motor is to the direct driving of calico-printing machines. At the Dunnell Print Works at Pawtucket a motor has been at work for 18 months driving a seven-roll printing machine. The uniformity of motion and the ease and smoothness with which the speed can be regulated have enabled the cloth to be printed at 50 per cent. greater speed than by the old steam-driven machine; and allowing for stoppages to change rolls, at least one-third greater output per machine is obtained.

Removing Arsenic from Copper.—One of the most deleterious impurities commonly found in commercial copper, and one which it is very difficult to eliminate, is arsenic. A very small percentage of this lowers the electrical and thermal conductivities of the metal, and renders it brittle. An addition to the ordinary Welsh process of refining copper has recently been brought out in America by a Mr. Stone. The modification is introduced immediately before the "poling" of the refined metal in a molten state with green timber. It consists in allowing the copper to oxidise until it is brittle and gives a dull red fracture, and then adding nitrate, carbonate or hydrate of potassium or sodium to the molten metal. The weight of salt or oxide added is equal to ten times the weight of arsenic to be separated out in the form of slag; and the metal is kept in a molten state for about 20 or 30 minutes after its addition. The refined metal is tapped into pigs, care being taken to prevent any admixture of the slag with the metal, and it is subsequently poled in the usual manner.

Thunderstorms.—Violent, widespread, and disastrous have been the recent thunderstorms which have resulted, probably, from the prolonged period of dry and hot weather. One remarkable feature of many of these storms has been the absence of rain, notwithstanding that the clouds have gathered thickly overhead. Another feature was the fall of large hailstones, in certain quarters, during the storms, resulting—as at Harrogate and Richmond, on Saturday last—in wholesale destruction of windows. The danger of using the telephone during thunderstorms has again been emphasised in several towns; and in a few cases fires seem to have resulted from telephone wires being struck. Chimneys appear to be specially attractive to the lightning; for, in a large proportion of the instances where houses have been struck the lightning seems to have descended the chimneys—probably on account of the higher conductivity of the hot air and wrought havoc in the rooms where chimneys terminated. The moral seems to be to avoid fireplaces during thunderstorms. The popular feeling against standing under trees seems to be justified by the great number of people and cattle either killed or severely injured while sheltering from the rain beneath trees. A man was killed at Boothen, near Stoke, while standing under a tree. At Hanley, in Staffordshire, one man was killed and four were injured, the men having taken shelter under the arches of the chimney of the electric light works. Near Scarborough considerable damage was done, a man being killed instantaneously at Ebberston.

Commercial Rivalries at the Chicago Exhibition.—"Much interest," says the *Western Electrician*, "has been manifested among the exhibitors in the Electricity Building over the controversy that has been in progress since the Westinghouse Electric and Manufacturing Company began work for its large electric sign on the inside of the southern wall of the Building." Up to the time that the Westinghouse Company had begun to get its exhibit in order it would appear that the most conspicuous feature in the Electricity Building was the General Electric Company's "Tower of Light." This, however, seems to have been surpassed as an advertising medium by a wall decoration of the Westinghouse Company, which was visible from all parts of the building. The overshadowing of their tower of light caused the representatives of the General Electric Company to immediately enter an emphatic protest against the wall decoration, it being asserted that the rival design was "wholly inartistic, amounting to nothing less than a disfigurement of the building, and totally out of place." To this sweeping impeachment the Westinghouse Company replied that Exhibitions were meant for advertising, and they intended to advertise themselves as much as possible. Mr. Barrett, head of the Electrical Department, supported the Westinghouse Company's contention. The matter was then carried to Mr. Burnham, the Director of Works, who, "after consultation with the Exposition artists," held that the Westinghouse advertisement was not in harmony with the rest of the building, and ordered it to be removed. Mr. Barrett, however, refused to obey, alleging that Mr. Burnham had no jurisdiction in the matter. Meanwhile the General Electric Company had endeavoured to induce other exhibitors to sign a petition praying for the removal of the obnoxious advertisement, but to no effect. The dispute was then carried as high as President Higinbotham, who upheld the Westinghouse Company, and it was finally taken higher still, namely, to the Council of Administration, who decided that the advertisement was to be allowed to remain.

An American Engineering Laboratory.—English professors, engaged in the wearing task of endeavouring to scrape together a few hundred pounds to enable them to equip their engineering laboratories with the irreducible minimum of apparatus, will read with mixed feelings a brief well-illustrated account of the new engineering laboratory at the Pennsylvania University, which appeared in the *Electrical World* of July 1st:—There are two buildings, comprising in all about 23,000 sq. ft. of floor. In the one-story boiler-house are seven boilers of the largest size. The manufacturers have taken special pains to make each a model of its kind, and the design has been to represent all varieties. All have been arranged to be tested by the students, and every appointment, while plain and simple, is of the most substantial and convenient kind. One section of this building is given up to the calorimeters, of which there are examples of all the well-known types. Immediately adjoining the boiler-house is the laboratory building, three and a-half stories high, and of mill construction. On the first floor are the engine-room and a mechanical laboratory. The former contains at present a 100 H.P. Westinghouse compound engine, driving Brush and United States dynamos, and a 100 H.P. Porter-Allen engine, driving Edison and Thomson-Houston dynamos. A 100 H.P. Armington and Sims engine, a 100 H.P. straight line engine, and a 50 H.P. Buckeye engine, together with five more direct and alternating-current dynamos of various types, are to be put in place in the near future. In the mechanical laboratory are a 45 H.P. Porter-Allen engine and a 30 H.P. Corliss engine. There are also several steam pumps and a large cistern and weir. The Porter-Allen engine supplies power for the adjoining wood and iron shops, but the Corliss engine is used for nothing but testing. The engine plant is completed by six other small engines which drive rotary fans. On the second floor are the library and reading rooms and a large mechanical and electrical laboratory. The third floor is given up to a drawing-room, a class-room and office, and an electrical laboratory. The fourth floor contain a blue print-room and a model room.

A GRAVITATIONAL AND ELECTROMAGNETIC ANALOGY.

BY OLIVER HEAVISIDE.

To form any notion at all of the flux of gravitational energy, we must first localise the energy. In this respect it resembles the legendary hare in the cookery book. Whether the notion will turn out to be a useful one is a matter for subsequent discovery. For this, also, there is a well-known gastronomical analogy.

Now, bearing in mind the successful manner in which Maxwell's localisation of electric and magnetic energy in his ether lends itself to theoretical reasoning, the suggestion is very natural that we should attempt to localise gravitational energy in a similar manner, its density to depend upon the square of the intensity of the force, especially because the law of the inverse squares is involved throughout.

Certain portions of space are supposed to be occupied by matter, and its amount is supposed to be invariable. Furthermore, it is assumed to have personal identity, so that the position and motion of a definite particle of matter are definite, at any rate relative to an assumed fixed space. Matter is recognised by the property of inertia, whereby it tends to persist in the state of motion it possesses; and any change in the motion is ascribed to the action of force, of which the proper measure is, therefore, the rate of change of quantity of motion, or momentum.

Let ρ be the density of matter, and $\mathbf{e}$ the intensity of force, or the force per unit matter, then

$$\mathbf{F} = \mathbf{e}\rho \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

expresses the moving force on ρ, which has its equivalent in increase of the momentum. There are so many forces nowadays of a generalised nature, that perhaps the expression "moving force" may be permitted for distinctness, although it may have been formerly abused and afterwards tabooed.

Now the force $\mathbf{F}$, or the intensity $\mathbf{e}$, may have many origins, but the only one we are concerned with here is the gravitational force. This appears to depend solely upon the distribution of the matter, independently of other circumstances, and its operation is concisely expressed by Newton's law, that there is a mutual attraction between any two particles of matter, which varies as the product of their masses and inversely as the square of their distance. Let $\mathbf{e}$ now be the intensity of gravitational force, and $\mathbf{F}$ the resultant moving force, due to all the matter. Then $\mathbf{e}$ is the space-variation of a potential, say,

$$\mathbf{e} = \nabla \mathrm{P}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

and the potential is found from the distribution of matter by

$$\mathrm{P} = \mathrm{pot}\,\frac{\rho}{c} = \Sigma\,\frac{\rho}{4\pi c r},$$

where c is a constant. This implies that the speed of propagation of the gravitative influence is infinitely great.

Now when matter is allowed to fall together from any configuration to a closer one, the work done by the gravitational forcive is expressed by the increase made in the quantity $\Sigma\frac{1}{2}\mathrm{P}\rho$. This is identically the same as the quantity $\Sigma\frac{1}{2}c\mathbf{e}^2$ summed through all space. If, for example, the matter be given initially in a state of infinitely fine division, infinitely widely separated, then the work done by the gravitational forcive in passing to any other configuration is $\Sigma\frac{1}{2}\mathrm{P}\rho$ or $\Sigma\frac{1}{2}c\mathbf{e}^2$, which therefore expresses the "exhaustion of potential energy." We may therefore assume that $\frac{1}{2}c\mathbf{e}^2$ expresses the exhaustion of potential energy per unit volume of the medium. The equivalent of the exhaustion of potential energy is, of course, the gain of kinetic energy, if no other forces have been in action.

We can now express the flux of energy. We may compare the present problem with that of the motion of electrification. If moved about slowly in a dielectric, the electric force is appreciably the static distribution. Nevertheless, the flux of energy depends upon the magnetic force as well. It may, indeed, be represented in another way, without introducing the magnetic force, but then the formula would not be sufficiently comprehensive to suit other cases. Now what is there analogous to magnetic force in the gravitational case? And if it have its analogue, what is there to correspond with electric current? At first glance it might seem that the whole of the magnetic side of electromagnetism was absent in the gravitational analogy. But this is not true.

Thus, if $\mathbf{u}$ is the velocity of ρ, then $\rho\mathbf{u}$ is the density of a current (or flux) of matter. It is analogous to a convective current of electrification. Also, when the matter ρ enters any region through its boundary, there is a simultaneous convergence of gravitational force into that region proportional to ρ. This is expressed by saying that if

$$\mathbf{C} = \rho\mathbf{u} - c\dot{\mathbf{e}}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

then $\mathbf{C}$ is a circuital flux. It is the analogue of Maxwell's true current; for although Maxwell did not include the convective term $\rho\mathbf{u}$, yet it would be against his principles to ignore it. Being a circuital flux, it is the curl of a vector, say

$$\mathrm{curl}\,\mathbf{h} = \rho\mathbf{u} - c\dot{\mathbf{e}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

This defines $\mathbf{h}$ except as regards its divergence, which is arbitrary, and may be made zero. Then $\mathbf{h}$ is the analogue of magnetic force, for it bears the same relation to flux of matter as magnetic force does to convective current. We have

$$\mathbf{h} = \mathrm{curl\ pot}\,\mathbf{C}, \quad . \quad . \quad . \quad . \quad . \quad (6)$$
$$= \mathrm{curl}\,\mathbf{A},$$

if $\mathbf{A} = \mathrm{pot}\,\mathbf{C}$. But, since instantaneous action is here involved, we may equally well take

$$\mathbf{A} = \mathrm{pot}\,\rho\mathbf{u}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

and its curl will be $\mathbf{h}$. Thus, whilst the ordinary potential P is the potential of the matter, the new potential $\mathbf{A}$ is that of its flux.

Now if we multiply (5) by $\mathbf{e}$, we obtain

$$\mathbf{e}\,\mathrm{curl}\,\mathbf{h} = \mathbf{e}\rho\mathbf{u} - \mathbf{e}c\dot{\mathbf{e}}, \quad . \quad . \quad . \quad . \quad . \quad (8)$$

or, which is the same,

$$\mathrm{conv}\,\mathbf{V}\mathbf{e}\mathbf{h} = \mathbf{F}\mathbf{u} - \dot{\mathrm{U}}, \quad . \quad . \quad . \quad . \quad . \quad (9)$$

if $\mathrm{U} = \frac{1}{2}c\mathbf{e}^2$. But $\dot{\mathrm{U}}$ represents the rate of exhaustion of potential energy, so $-\dot{\mathrm{U}}$ represents its rate of increase, whilst $\mathbf{F}\mathbf{u}$ represents the activity of the force on ρ, increasing its kinetic energy. Consequently, the vector $\mathbf{V}\mathbf{e}\mathbf{h}$ expresses the flux of gravitational energy. More strictly, any circuital flux whatever may be added. This $\mathbf{V}\mathbf{e}\mathbf{h}$ is analogous to the electromagnetic $\mathbf{V}\mathbf{E}\mathbf{H}$ found by Poynting and myself. But there is a reversal of direction. Thus, comparing a single moving particle of matter with a similarly-moving electric charge, describe a sphere round each. Let the direction of motion be the axis, the positive pole being at the forward end. Then in the electrical case the magnetic force follows the lines of latitude with positive rotation about the axis, and the flux of energy coincides with the lines of longitude from the negative pole to the positive. But in the gravitational case, although $\mathbf{h}$ still follows the lines of latitude positively, yet since the radial $\mathbf{e}$ is directed to instead of from the centre, the flux of energy is along the lines of longitude from the positive pole to the negative. This reversal arises from all matter being alike and attractive, whereas like electrifications repel one another.

The electromagnetic analogy may be pushed further. It is as incredible now as it was in Newton's time that gravitative influence can be exerted without a medium; and, granting a medium, we may as well consider that it propagates in time, although immensely fast. Suppose, then, instead of instantaneous action, which involves

$$\mathrm{curl}\,\mathbf{e} = 0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

we assert that the gravitational force $\mathbf{e}$ in ether is propagated at a single finite speed v. This requires that

$$v^2\nabla^2\mathbf{e} = \ddot{\mathbf{e}}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

for this is the general characteristic of undissipated propagation at finite speed. Now,

$$\nabla^2 = \nabla\,\mathrm{div} - \mathrm{curl}^2,$$

so in space free from matter we have

$$-v^2\,\mathrm{curl}^2\,\mathbf{e} = \ddot{\mathbf{e}}. \quad . \quad . \quad . \quad . \quad . \quad (12)$$

But we also have, by (5),

$$-\mathrm{curl}\,\mathbf{h} = c\dot{\mathbf{e}}, \quad . \quad . \quad (13)$$

Digitized by Google

away from matter. This gives a second value to $\ddot{\mathbf{e}}$, when we differentiate (13) to the time, say

$$\ddot{\mathbf{e}} = -\frac{1}{c}\operatorname{curl}\dot{\mathbf{h}}. \quad . \quad . \quad . \quad . \quad . \quad (14)$$

So, by (12) and (14), and remembering that we have already chosen $\mathbf{h}$ circuital, we derive

$$cv^2 \operatorname{curl}\mathbf{e} = \dot{\mathbf{h}}. \quad . \quad . \quad . \quad . \quad . \quad (15)$$

Or, if μ is a new constant, such that

$$\mu c v^2 = 1, \quad . \quad . \quad . \quad . \quad . \quad (16)$$

then (15) may be written in the form

$$\operatorname{curl}\mathbf{e} = \mu\dot{\mathbf{h}}. \quad . \quad . \quad . \quad . \quad . \quad (17)$$

To sum up, the first circuital law (5), or

$$\operatorname{curl}\mathbf{h} = \rho\mathbf{u} - c\dot{\mathbf{e}}, \quad . \quad . \quad . \quad . \quad (18)$$

leads to a second one, namely (17), if we introduce the hypothesis of propagation at finite speed. This, of course, might be inferred from the electromagnetic case.

In order that the speed v should be not less than any value that may be settled upon as the least possible, we have merely to make μ be of the necessary smallness. The equation of activity becomes, instead of (9),

$$\operatorname{conv} V\mathbf{eh} = \mathbf{Fu} - \dot{\mathrm{U}} - \dot{\mathrm{T}}, \quad . \quad . \quad . \quad (3)$$

if $\mathrm{T} = \frac{1}{2}\mu\mathbf{h}^2$. The negative sign before the time-increase of this quantity points to exhaustion of energy, as before. If so, we should still represent the flux of energy by $V\mathbf{eh}$. But, of course, T is an almost vanishing quantity when μ is small enough, or v big enough. Note that $\mathbf{h}$ is not a negligible quantity, though the product $\mu\mathbf{h}$ is. Thus results will be sensibly as in the common theory of instantaneous action, although expressed in terms of wave-propagation. Results showing signs of wave-propagation would require an inordinately large velocity of matter through the ether. It may be worth while to point out that the lines of gravitational force connected with a particle of matter will no longer converge to it uniformly from all directions when the velocity v is finite, but will show a tendency to lateral concentration, though only to a sensible extent when the velocity of the matter is not an insensible fraction of v.

The gravitational-electromagnetic analogy may be further extended if we allow that the ether which supports and propagates the gravitational influence can have a translational motion of its own, thus carrying about and distorting the lines of force. Making allowance for this convection of $\mathbf{e}$ by the medium, with the concomitant convection of $\mathbf{h}$, requires us to turn the circuital laws (17), (18) to

$$\operatorname{curl}(\mathbf{e} + \mu V\mathbf{qh}) = \mu\dot{\mathbf{h}}, \quad . \quad . \quad . \quad . \quad (19)$$

$$\operatorname{curl}(\mathbf{h} + cV\mathbf{eq}) = \rho\mathbf{u} - c\dot{\mathbf{e}}, \quad . \quad . \quad . \quad (20)$$

where $\mathbf{q}$ is the velocity of the medium itself.

It is needless to go into detail, because the matter may be regarded as a special and simplified case of my investigation of the forces in the electromagnetic field, with changed meanings of the symbols. It is sufficient to point out that the stress in the field now becomes prominent as a working agent. It is of two sorts, one depending upon $\mathbf{e}$ and the other upon $\mathbf{h}$, analogous to the electric and magnetic stresses. The one depending upon $\mathbf{h}$ is, of course, insignificant. The other consists of a pressure parallel to $\mathbf{e}$ combined with a lateral tension all round it, both of magnitude $\frac{1}{2}c\mathbf{e}^2$. This was equivalently suggested by Maxwell. Thus two bodies which appear to attract are pushed together. The case of two large parallel material planes exhibits this in a marked manner, for $\mathbf{e}$ is very small between them, and relatively large on their further sides.

But the above analogy, though interesting in its way, and serving to emphasise the non-necessity of the assumption of instantaneous or direct action of matter upon matter, does not enlighten us in the least about the ultimate nature of gravitational energy. It serves, in fact, to further illustrate the mystery. For it must be confessed that the exhaustion of potential energy from a universal medium is a very unintelligible and mysterious matter. When matter is infinitely widely separated, and the forces are least, the potential energy is at its greatest, and when the potential energy is most exhausted, the forces are most energetic!

Now there is a magnetic problem in which we have a kind of similarity of behaviour, viz., when currents in material circuits are allowed to attract one another. Let, for completeness, the initial state be one of infinitely wide separation of infinitely small filamentary currents in closed circuits. Then, on concentration to any other state, the work done by the attractive forces is represented by $\Sigma\frac{1}{2}\mu\mathbf{H}^2$, where μ is the inductivity and $\mathbf{H}$ the magnetic force. This has its equivalent in the energy of motion of the circuits, or may be imagined to be so converted, or else wasted by friction, if we like. But, over and above this energy, the same amount, $\Sigma\frac{1}{2}\mu\mathbf{H}^2$, represents the energy of the magnetic field, which can be got out of it in work. It was zero at the beginning. Now, as Lord Kelvin showed, this double work is accounted for by extra work in the batteries or other sources required to maintain the currents constant. (I have omitted reference to the waste of energy due to electrical resistance, to avoid complications.) In the gravitational case there is a partial analogy, but the matter is all along assumed to be incapable of variation, and not to require any supply of energy to keep it constant. If we asserted that $\frac{1}{2}c\mathbf{e}^2$ was stored energy, then its double would be the work done per unit volume by letting bodies attract from infinity, without any apparent source. But it is merely the exhaustion of potential energy of unknown amount and distribution.

Potential energy, when regarded merely as expressive of the work that can be done by forces depending upon configuration, does not admit of much argument. It is little more than a mathematical idea, for there is scarcely any physics in it. It explains nothing. But in the consideration of physics in general, it is scarcely possible to avoid the idea that potential energy should be capable of localisation equally as well as kinetic. That the potential energy may be itself ultimately kinetic is a separate question. Perhaps the best definition of the former is contained in these words:—Potential energy is energy that is not known to be kinetic. But, however this be, there is a practical distinction between them which it is found useful to carry out. Now, when energy can be distinctly localised, its flux can also be traced (subject to circuital indeterminateness, however). Also, this flux of energy forms a useful working idea when action at a distance is denied (even though the speed of transmission be infinitely great, or be assumed to be so). Any distinct and practical localisation of energy is therefore a useful step, wholly apart from the debatable question of the identity of energy advocated by Prof. Lodge.

From this point of view, then, we ought to localise gravitational energy as a preliminary to a better understanding of that mysterious agency. It cannot be said that the theory of the potential energy of gravitation exhausts the subject. The flux of gravitational energy in the form above given is, perhaps, somewhat more distinct, since it considers the flux only and the changes in the amount localised, without any statement of the gross amount. Perhaps the above analogy may be useful, and suggest something better.

MEASURING MAGNETIC FIELDS.

BY ALEX. RUSSELL, M.A.

A quick method of measuring the horizontal strength (H) of a magnetic field is very useful in a laboratory or testing room. The following method of measuring H appears at first sight very primitive, but it is capable, in the hands of a careful experimenter, of giving results accurate enough for many practical purposes, and the apparatus required is only of the most ordinary description. In the rough magnetometer test, as done by students in physical laboratories, the apparatus need be only of the most simple description; but this method hardly measures H at a point unless we have the magnet very small, in which case all kinds of errors creep in. The other common methods require special and carefully constructed apparatus.

The instruments required for the method are an ammeter and a small compass needle; one of those sold as "charms"

Digitized by Google

for watch-chains is very suitable. The needle is placed at the point where the strength of the field is to be measured, and a long hanging vertical wire, with a current flowing in it, is brought near the needle. When the wire is at a certain distance from the needle on a line drawn through the centre of

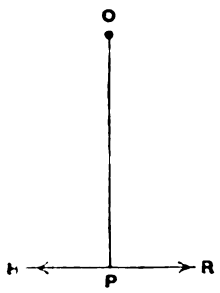

Fig. 1.

the needle perpendicular to its length, the resultant magnetic force is so feeble at the point that the needle rests in almost any position. Let P (Fig. 1) be the point, and suppose the wire to cut the plane of the paper at right angles at O. If the current be flowing upwards and be A amperes, the magnetic

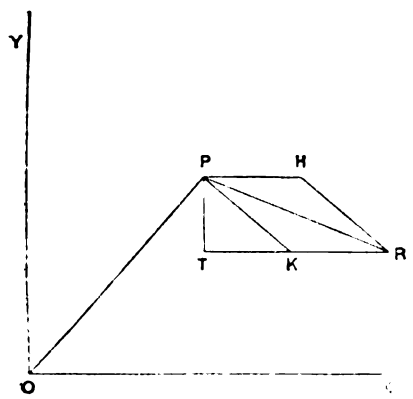

Fig. 2.

force at P due to the current is at right angles to O P in the direction P R, and is equal to $\frac{2A}{10 \cdot OP}$. Then, if the magnetic force due to the current exactly neutralises the field,

$$H = \frac{A}{5 \cdot OP} \text{ C.G.S. units.}$$

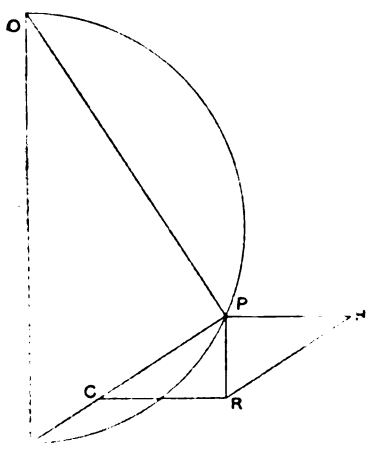

Fig. 3.

The behaviour of the needle at this point is peculiar. On moving the wire from O towards P the needle points towards R, on moving it from P it points towards H. Moving the wire a very little way parallel to R H the needle points towards the wire nearly, and on moving it slightly in the opposite direction the needle points away from the wire. The reason of this can be easily seen by drawing the resultant force at P in the two positions of O by means of the parallelogram of forces.

The case of a uniform magnetic field disturbed by a current flowing in a wire is of special importance. A diagram of the lines of force in this case is given in Clerk Maxwell's "Electricity," Vol. II., plate XVII. As it is useful for our purpose to know the directions of the lines of force nearer the neutral point than he has shown on his diagram, we shall find the algebraical equation to the lines of force and then draw the lines of force through points near the neutral point. The ordinary method of tracing the lines of force, practically, is by means of a small compass, the needle pointing always in the direction of the resultant force and, therefore, always being a tangent to the line of force which passes through the point.

In Fig. 2 let O be the section of the wire by the plane of the paper, and let O X be the direction of the earth's lines. Let (x, y) be the co-ordinates of P, and let the angle P O X be θ. The forces at P are P H parallel to O X and equal to H and P K at right angles to O P and equal to $\frac{A}{5 \cdot OP}$. Let P R be their resultant. Draw P T at right angles to K R, produced. Then for the line of force through P,

$$\frac{dy}{dx} = -\tan PRT = -\frac{\frac{A}{5 \cdot OP}\cos\theta}{H + \frac{A}{5 \cdot OP}\sin\theta}.$$

Also $\cos\theta = \frac{x}{OP}$, $\sin\theta = \frac{y}{OP}$ and $OP^2 = x^2 + y^2$.

Hence $$5H(x^2+y^2)\frac{dy}{dx} + Ay\frac{dy}{dx} = -Ax.$$

$$\therefore \frac{A}{10H(x^2+y^2)}\cdot\frac{d}{dx}(x^2+y^2) + \frac{dy}{dx} = 0.$$

$$\therefore \frac{A}{10H}\log(x^2+y^2) + y = \text{constant},$$

$$\therefore x^2 + y^2 = Me^{-\frac{10Hy}{A}} \quad \ldots\ldots \quad (1)$$

By giving different values to M we get the equations to the lines of force. It is easily seen that $\frac{dy}{dx}$ is infinite whenever a line of force cuts the circle

$$x^2 + y^2 + \frac{A}{5H}y = 0.$$

Hence at all points on this circle, except the neutral point, the needle will point east and west, or west and east.

It is easy to give a geometrical proof of this theorem. The

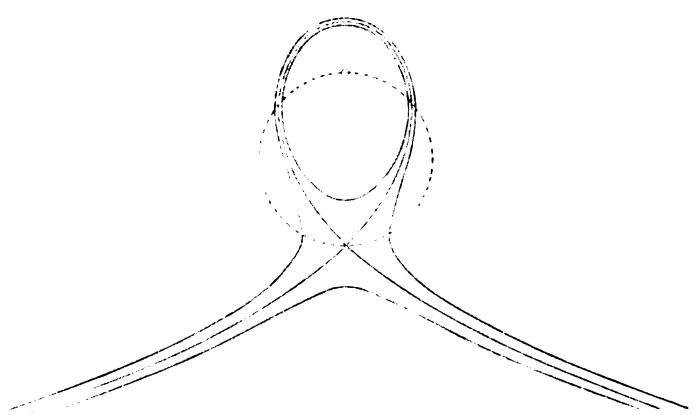

Fig. 4.—Directions of Horizontal Magnetic Force near a Vertical Wire Carrying a Current of 2 amperes.

resultant of the horizontal component of the earth's field and the magnetic force due to the current in the wire at a point coincides in direction with the tangent to the line of force passing through the point. Hence (Fig. 3) if P H and P C be the directions of the forces due to the earth and the wire respectively, and if P R be the diagonal of the parallelogram which

Digitized by Google

has P H and P C as adjacent sides, then P R is the direction of the needle. If this is parallel to O A,

$$\frac{OP}{OA}=\frac{CR}{CP}=\frac{5H.OP}{A}$$

$\therefore OA=\frac{A}{5H}=$ constant. Therefore P lies on the circumference of a circle whose diameter is equal to O A. The equation to the line of force through the neutral point is

$$x^2+y^2=\frac{A^2}{25H^2}e^{-2-\frac{10H}{A}y}.$$

This curve is shown in Fig. 4 for the case of A = 2 amperes, and H = 0·18 C.G.S. unit. At points where the lines of force cut the circle shown in the figure, the direction of the lines is parallel to O A.

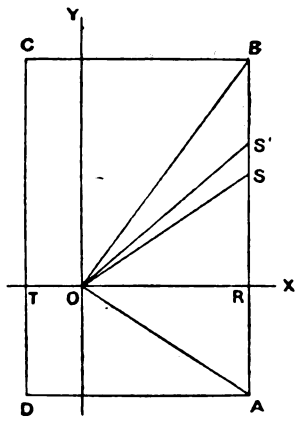

Fig. 5.

We must now consider the effect of the wires leading up to the hanging wire. The simplest case is when the wire is in the shape of a rectangle with its plane east and west (Fig. 5). We shall find an expression for the strength of the field at a point O in the plane of the rectangle, due to a current i (C.G.S. units) flowing in the wire. Let O X and O Y be perpendicular to the sides of the rectangle, and let A R = a, R B = b, and O R = c. Then if F be the strength of the field at O, due

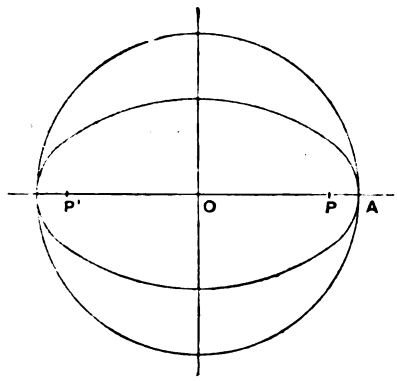

Fig. 7.

to the current in D C, we get by considering the action of an element S S' ($=dy$) of the wire that

$$F=\int_{-a}^{b}\frac{i\,c\,dy}{\{c^2+y^2\}^{\frac{3}{2}}}$$

$$=\frac{i}{c}\left\{\frac{y}{(c^2+y^2)^{\frac{1}{2}}}\right\}_{-a}^{b}$$

$$=\frac{i}{c}\left\{\frac{a}{(c^2+a^2)^{\frac{1}{2}}}+\frac{b}{(c^2+b^2)^{\frac{1}{2}}}\right\}$$

$$=\frac{i}{OR}\{\sin ROB+\sin ROA\}$$

Exactly similar expressions hold for the forces due to the three other sides of the rectangle. Hence the exact formula in this case is—

$$H=\frac{i}{OR}\{\sin ROA+\sin ROB\}+\ldots+\ldots+\ldots$$

If D C is three metres long, B C four metres, O T 10cms., and if O is equi-distant from the two horizontal sides of the rectangle, then an error a little over 1 per cent. is introduced by using the approximate formula $\frac{2i}{OT}$. This error can be got rid of practically either by placing the plane of the rectangle north and south, and finding the point east or west of the hanging wire where the needle points directly towards it, or reversing the current and taking the mean of the two values found for H by the simple formula.

This compass method can also be very instructively applied to measure the field of force inside a flat coil of wire. We set the coil with its plane east and west, and place the compass at the point where we wish to measure the strength of the field, and then pass a small current through the coil (in the proper direction), increasing the current until the needle turns round. Suppose the current in the wire when the field at the point is neutralised is A' amperes, then obviously when a current A flows in the wire the strength of the field at the point due to the current equals H A/A', where H is the horizontal intensity of the earth's field at the point. Similarly we can map out the intensity of the field at other points in the plane of the coil in C.G.S. units.

The case of a circular wire is specially important, and the formula for the strength of the field at a point in the plane of the wire is not so well known as it deserves to be. Let P (Fig. 6) be a point in the plane of the wire, and let O be

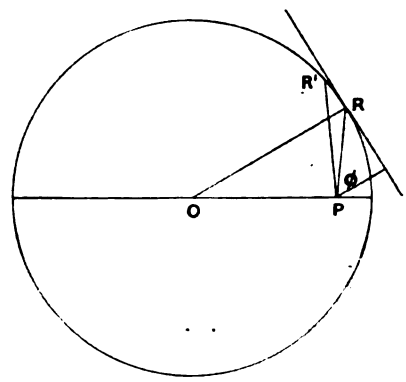

Fig. 6.

the centre and R the radius of the wire. Then if F be the strength of the field due to a current i in the wire,

$$F=\int\frac{i\,ds}{r^2}\times\frac{p}{r}\text{ (usual notation)},$$

$$=\int_0^{2\pi}\frac{i\,d\phi}{r}\text{ since }p\,ds=r^2\,d\phi.$$

Now $r=\sqrt{R^2-a^2\sin^2\phi}-a\cos\phi$, where O P = a,

$$\therefore\ \frac{1}{r}=\frac{\sqrt{R^2-a^2\sin^2\phi}+a\cos\phi}{R^2-a^2}.$$

Hence

$$F=\frac{i}{R^2-a^2}\int_0^{2\pi}\sqrt{R^2-a^2\sin^2\phi}\,d\phi,$$

$$+\frac{ia}{R^2-a^2}\int_0^{2\pi}\cos\phi\,d\phi.$$

Now, if we describe an ellipse which has O for its centre, P for a focus, and 2 R as major axis (Fig. 7), the circumference of this ellipse is equal to $\int_0^{2\pi}\sqrt{R^2-a^2\sin^2\phi}\,d\phi$.

Hence

$$F=\frac{\text{Circumference of ellipse}\times i}{R^2-a^2}.$$

We can thus calculate F at each point by mechanically describing the ellipse by a thread and two pins, measuring the circumference by means of a thread, in the ordinary laboratory way, and then substituting in the formula. The circumference of the ellipse can also be calculated from the formula,

$$\frac{\pi}{2}\{R+\sqrt{R^2-a^2}+\sqrt{4R^2-2a^2}\},\text{ up to }a=0{\cdot}8\,R.$$

Digitized by Google

It is a very instructive exercise to map out the strength of a field inside a circular wire by the compass method, and then check the results by means of the above formula.

The method can also be applied to calculating the coefficient of self-induction of a wire bent into a large plane closed curve. The strength of the field very near the wire can be calculated by the formula $\frac{A}{5r}$, and at other points by the compass method.

Suppose F the strength of the field at dS due to unit current, and L the coefficient of self-induction, then

$$L = \Sigma F d S.$$

Hence, since F is known at every point L can be calculated.

ADJUSTABLE CARBON RHEOSTAT.

The Wheatstone Rheostat was probably the earliest form of adjustable resistance, in which a gradual alteration of a resistance was aimed at without any attempt at accurate measurement. In many electrical operations, such as telegraphy,

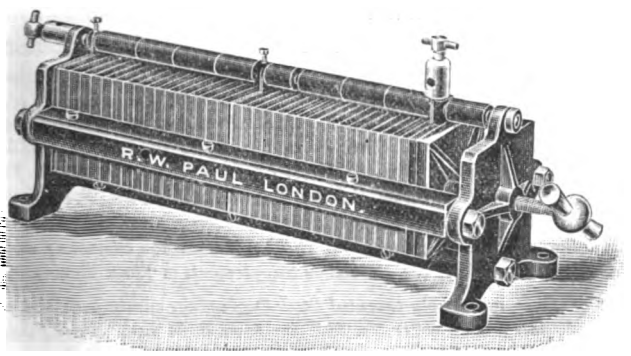

FIG. 1.

definite resistances wound on coils and connected by plugs or switches are used exclusively; but in many modern applications, especially where it is desired to control large currents, adjustable resistances are indispensable. The 10 or 20 point switches, and a number of coils of iron or German silver are often used, but the discontinuity of such an arrangement, to say nothing of the space which it occupies, is an obvious disadvantage.

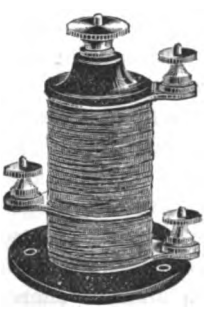

FIG. 2.

The fact that the resistance of carbon blocks alters under pressure was long ago made use of by Brush in his arc lighter regulator, and we have recently received from Mr. R. W. Paul, particulars of two forms of carbon rheostats; the one for heavy currents, and the other for small currents.

The large rheostat shown in the accompanying illustration (Fig. 1) consists of a pile of 40 retort-carbon plates, 3½in. square, by ⅜in. thick. These are held in a metal frame insulated from the circuit, and are secured by a steel screw. The resistance may be varied from 25 ohms to $\frac{1}{25}$th of an ohm, and still lower resistances may be obtained by the use of an intermediate terminal plate. For short periods this rheostat will carry 100 amperes without serious overheating. For laboratory use in the neighbourhood of galvanometers and other sensitive magnetic instruments, the frame and fittings may be made of gun metal. Such a rheostat depends to a certain extent upon the elasticity of the carbon plates.

For smaller currents another form (Fig. 2) of carbon is used, viz., Varley's carbonised cloth, 150 sheets of stout cloth are built into a pile 1⅝in. in diameter, 2½in. high, with a hole down the centre ½in. in diameter. The pressure is applied by a screw passing down the centre. The resistance between the outside terminals varies (*a*) with the degree of "cementation" of the cloth, (*b*) with the pressure applied to the column by the milled nut. When the nut allows the elasticity of the sheets to extend the column to a length of 2½in. the resistance is 10 to 15 ohms, the carbon being well cemented. When the nut is turned so as to give the maximum safe compression, *i.e.*, length of column 2in., the resistance is approximately $\frac{1}{10}$th of an ohm. By using a different quality of carbonised cloth in which the process of carbonisation has not been carried so far, resistances of 20 to 500 ohms may be constructed, the instrument being of the same dimensions. Owing to the springiness of the cloth, ordinary shaking or jarring does not perceptibly vary the resistance. As in the large rheostats, an extra terminal is placed at about one-third from the bottom of the pile, so as to reduce the above resistances to one-third or two thirds of their value. With a 10 ohm rheostat, that is to say, with an instrument whose maximum resistance is 10 ohms, a current of 4 amperes *may* be passed, but it becomes too hot to hold when it is dissipating about 160 watts.

FUSION AND VOLATILISATION OF VARIOUS SUBSTANCES IN THE ELECTRIC ARC.*

BY H. MOISSAN.

When we have wished to condense the vapours of difficultly volatilised bodies at a high temperature, we have employed a metal tube, cooled internally by a current of water, and in these experiments we have used a U-tube of copper, of 15mm. diameter conveying a current of water at a pressure of 10 atmospheres. The bend of the U-tube was introduced into the electric arc, over the little crucible containing the substance to be volatilised. By means of the arrangement adopted the vapours condensed in abundance on the cold tube. A fragment of copper, weighing 103 grammes, was placed in the crucible, and a current of 350 amperes, at a pressure of 70 volts, was passed for five minutes. Brilliant flames, 4 or 5cm. long, accompanied by dense yellow fumes, poured from the crucible, and an abundance of metallic copper condensed in the U-tube. The experiment repeated, but with silver instead of copper, gave a mixture of amorphous silver and molten globules in the cold tube. Platinum and aluminium were also quickly volatilised and condensed in metallic globules in the tube. From tin a dense incrustration of the oxide was obtained.

With a current of 380 amperes at 80 volts, the volatilisation of silicon was obtained, and globules of this element, readily soluble in nitric and hydrofluoric acid, collected upon the condensing surface of the tube. With the same current at the same pressure, carbon placed in the crucible, in the form of large lumps, quickly became changed into *graphite*; and, at the end of the experiment, transparent particles of a chestnut colour were found on the cold tube. Mr. Berthelot has already discovered the existence of such a chestnut coloured carbon of low specific gravity. With a current of 400 amperes lime was volatilised, and an amorphous powder of calcic oxide was deposited. Magnesia, which is more difficult to volatilise than lime, gave a similar result. Mr. Daubrée has remarked that the carbon now found in organic compounds was originally combined with metals in the state of metallic carbonates. The electric furnace seems well to reproduce the conditions of that remote geological period. It is probable that these compounds exist at a high temperature in some of the stars.

Electrical Communication with Lighthouses.—The Royal Commission on electrical communication with lighthouses and lightships have now commenced their inspection of lighthouses and lightships on the South and East Coasts of Ireland and the Isle of Man. They intend to visit Bangor and Belfast Lough, after inspecting the "South Rock" and "Skull Martin" light vessels from Her Majesty's ship "Enchantress."

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Paley, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; and Sir James Anderson, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

THE ELECTROLYSIS OF STEAM.

By far the most striking and important point involved in Prof. J. J. THOMSON's Paper on "The Electrolysis of Steam," which we reprint elsewhere, and which was read before the Royal Society last March, is the fact that the elements hydrogen and oxygen exhibit either an electro-positive or an electro-negative property, according to the length and character of the spark which is passed through the super-heated steam. When the electric discharge is of the nature of an arc, or continuous stream, the electrolytic hydrogen is evolved at the *positive* electrode, while, when that element appears at the *negative* electrode, the discharge shows all the characteristics of a spark, though it would appear that the hydrogen may be evolved at either of the electrodes when there are separate sparks passing through the steam. The whole phenomenon is enveloped in mystery, and the explanation offered by the author of the Paper can only be regarded as a tentative one. Does the atom-charge of the dissociated hydrogen really depend on the state of electrical stress under which it is liberated, and on the time which has elapsed since the passage of a previous discharge? Does an electrical discharge through an insulating gas really metamorphose the gas into a temporary and very unstable isomer or allotrope, which enables conduction readily to take place? If so, the explanation of the reversed electro-chemical property is not a difficult matter. But, on the other hand, the assumption that these things do occur calls up innumerable difficulties. For the complete reversal of the atom charge under electric stress could only occur, according to existing notions, under a complete reconstruction of the atom itself, which postulates more than can be readily granted by our scientific imagination; while the assumption that the passage

Digitized by Google

of the arc through steam surrounds the discharge with a modified gas in the form of negative hydrogen *mixed* with positive oxygen can only be accepted, as far as we are able to gather, on the ground that it suits the particular phenomenon we are considering.

The test experiments by which Prof. THOMSON discovered that oxygen enveloping an arc becomes positively charged, and hydrogen negatively, deal, of course, with atoms of these elements in the aggregate; and it seems probable from them that electrification of the gas in bulk is the key to the solution of this problem. It seems possible, however, that, under certain conditions in which the mean free path of the ion atoms would be sufficiently long, the reversal of the gas at the electrode may be caused by the repulsion of the electrified gas from the electrode at which it is dissociated, and its ultimate liberation at the opposite electrode. Since this would only occur under certain magnitudes of stress, and would take place simultaneously with both ions, the supposition would not necessarily be inconsistent with CLAUSIUS's modification of GROTTHUS's hypothesis of electrolysis. It is interesting to notice that in the same number of the *Proceedings* of the Royal Society with Prof. THOMSON's Paper, there is a Paper by Dr. ALEX. SCOTT "On the Composition of Water by Volume," in which an attempt has been made to show that the volumetric proportions of hydrogen to oxygen in water is greater than two to one. Inasfar as the correctness of this assumption would affect the complexity of the molecule of water (and of steam), it might throw some light upon Prof. THOMSON's results; but it seems probable that the discrepancy arises from some difference between the purely physical properties of the hydrogen and oxygen, or from the formation of ozone in the latter.

MUNICIPAL TELEPHONY.

As we mentioned some little time ago, a Special Committee of the Glasgow Town Council was appointed to consider the *pros* and *cons* of establishing a municipal telephone service within the bounds of what is now frequently called "Greater Glasgow," and we ventured to suggest that municipal telephones might possibly prove, after due consideration and experiment, to be the best way out of the telephone *imbroglio* which at present exists in this fortunate isle. At a meeting of this Special Committee on Monday last it was unanimously decided to recommend that the Town Council should apply to the Postmaster-General for a telephone licence. Glasgow has always favoured municipalisation, and the experiment of municipalising the telephones, should it ever be put into practice, will, therefore, be carried out on congenial soil. Some forty years ago the Glasgow Corporation bought up the existing water companies and constructed immense works for the purpose of bringing water into the city from Loch Katrine, some thirty-four miles off, something like £3,500,000 having been spent upon the enterprise up to date. In 1869 the gas works were bought up. At the beginning of last year the electric light works were purchased, and on July 1st next the Glasgow tramway system will also be taken over and worked by the Corporation. The addition of municipal telephony to such varied and extensive duties should not, therefore, prove a fatal tax upon the civic energies of Glasgow. At the meeting of the Committee on Monday an exhaustive memorandum dealing with the whole of the subject of telephony was submitted by the convener. The case for a good telephone service is sufficiently strong without the addition of what may be termed special pleading. Because telephone rentals in Holland and Scandinavia are of the order of £3 a year it does not follow that £10 is an extravagant charge in the United Kingdom. Such statements require to be accompanied by data as to the efficiency of the systems and the general cost of labour and living in the countries mentioned. The convener further mentioned that reliable and detailed estimates had been prepared, showing that the latest and best telephone system could be laid down in Glasgow within the municipal radius for a capital expenditure of about £15 per subscriber, and that a £5 annual rental was feasible. We trust these anticipations may be realised in actual practice; but it must be remembered that most engineering estimates are notoriously over sanguine.

It is, of course, advisable that certain public services should be carried out by a public body, and not even the most inveterate individualist can offer serious objections to the municipalisation of the water, fire, police, sanitary, and street lighting services. A *doctrinaire*, indeed, could easily prove to demonstration that whilst street lighting pertains to a municipality private lighting does not; but the plain business man would admit that whoever undertakes one should undertake both. The encouragement of unlimited talk is, however, a considerable extension of the sphere of municipal activity, and we shall not be at all sorry to see the first large scale experiment carried out at a safe distance across the border.

REVIEWS.

Electrical Measurements and other Advanced Primers of Electricity. By EDWIN J. HOUSTON, A.M. (New York: W. J. Johnston Company, Times Buildings. London: Whittaker and Co.)

The Elementary Primers, upon which this book is an advance, were written at the time of the Philadelphia International Electrical Exhibition, and were designed to aid a public quite unacquainted with the principles of electrical science. The present series of Primers, although an advance upon the first, are of a strictly popular nature, and are written for a public which is assumed to have assimilated a certain amount of electrical knowledge—at least, in so far as the applications of electricity are concerned—in the interval. The work is essentially American in almost all its interests and in the style in which its matter is arranged; but it will no doubt be read with profit by an English public. The ground covered is not so wide, but the character of the Primers is nearly the same, as the series of Primers which are known to our readers; and we are glad to see that the practice of adding to each Primer the name of some text-book which bears particularly on the subject has been faithfully followed. The greater part of the book is taken up with electrical distribution of power and the theory and practice of alternating currents, which are dealt with in a clear and simple style, and are brought up to date. Perhaps the most interesting Primer in the series is No. IX., on high-frequency currents, which deals with the researches of Tesla and others on this subject, and is copiously illustrated.

Electric Lighting and Power Distribution. Part II. By W. P. MAYCOCK. (London: Whittaker and Co.)

We have already reviewed Part I. of this book in *The Electrician*, Vol. XXX., p. 602. Part II. deals with more practical matter, and contains a very good descriptive chapter on modern dynamos and alternators. The succeeding chapter on motors, is also well written. Dynamo theory is continued in Chapter X.; but the evident desire to maintain a very elementary style has led the author to generalise in a rather misleading manner. For example, we are told that the characteristic curves of "all series machines are more or less alike," and the student is led to believe that the characteristic of a series dynamo is in all parts an ascending curve. What unconscious humour there is in the footnote to page 295: "Many writers confuse the parallel-series and the series-

Digitized by Google

parallel arrangements." Unhappy writers! but we must own to being among their number. If such terms as "parallel-series" and "series-parallel" are required by the syllabus of examinations of the august Guild for which the book is prepared, it is quite time that the requirement ceased. On the whole, this second part is considerably better than Part I.

Premiers Principes d'Electricite Industrielle. By PAUL JANET. (Paris: Gauthier-Villars et Fils.)

This work is the reproduction, in an extended form, of a series of lectures which were delivered by the author at Grenoble, under the auspices of the Municipality, in the early part of 1892. As a popular treatise on electro-technics the book should find numerous readers; for, while the style is clear and the matter is simply rendered, popular treatment has not been attempted by means of misleading generalisations or that slurring over of details which we find in too many of the works which appeal to a non-scientific public. Here is interesting and instructive reading combined; and even a serious student of technical electricity may do himself good by perusing it. The various chapters deal with secondary cells, dynamos, alternators, transformers, and polyphase currents, with an introduction giving just enough theory to knit the practical parts together.

Electricity and Magnetism: A Popular Introduction. By S. R. Bottone. (London: Whittaker and Co.)

The author of this little book writes that its object "is to present an easy and attractive introduction to the sciences of electricity and magnetism. The work is not intended as a text-book. . . . Care has been taken to impart exact knowledge, that will not have to be unlearnt." We quite support the author's intention not to offer this work as a text-book; and when we read of the care which has been expended in making the book exact, we regret that such care should have been in so many cases unsuccessful. In other words, we do *not* agree that the knowledge which is imparted is exact, or that it would not have to be unlearned. Witness the following:—On page 15 we read: "An attentive consideration of these lines of force, as thus depicted by the iron filings, will lead us to the conclusion that the influence of a magnet, like that of all radiating forces, must, from the very nature of things, decrease *inversely as the square of the distance*." The italics are not our own, but the author's. Is it possible to crowd together more errors into one small sentence than are crowded into this? An attentive study of iron filings can never lead to an exact mathematical law; if it could, the law of inverse squares would not apply to the case cited. Magnetism is not, as Mr. Bottone infers, analogous to "all radiating forces" in this respect; and his inference, from "the very nature of things" is illogical and superfluous. The attribution of terrestrial magnetism to ferruginous soils, on page 21, is purely a gratuitous assumption, there being no evidence of any such cause. According to Mr. Bottone, the modern theory of electricity, "generally known as the *molecular* or *mechanical* theory," is one in which "the fundamental idea is that during excitation, whether by friction, percussion, chemical action, or motion before the poles of a magnet, the normal condition of a body is altered, its molecules are set in motion, probably rotary, with the axes of rotation all in one direction, or "polarised," and this motion produces a kind of strain between molecule and molecule, in one direction in the excited body, and in the opposite direction in the exciting body." We do not know whose "modern theory" all this is supposed to represent; but, whatever may be its origin, we have no hesitation in saying that it is utterly erroneous and unscientific. These, and many other statements in the book, the reader must unlearn when he passes from the "introduction," offered by Mr. Bottone, to the study of the real science of electricity.

A Guide to Electric Lighting. By S. R. BOTTONE. (London: Whittaker and Co.)

The second edition of this little book lies before us. Ten thousand of "the public" have paid their shilling, and have been guided into the mysteries of electric lighting. What is precisely that this public may have desired to know is as much of a mystery as anything electrical is to it. Perhaps it was to satisfy its innate love of being mystified that ventured along this way. If so, the information on page of the guide-book, that "electricity itself is but another form of motion, which requires power to produce it," ought serve the purpose very well! Again, we can fancy some one asking the guide, "But what *is* an ampere-turn?" which the guide makes answer (page 45), "By ampere-turn is meant the number of turns of wire equivalent to a single turn carrying one ampere." And with a murmur of approval, and many a knowing nod, the crowd would then pass along to see "the next thing." And the things to be seen are very curious—so antiquated, so utterly unlike the electric lighting machinery the public sees nowadays, that it must feel gratified at the sight. Here, on page 14, is a Leclanché cell, with pages of description to follow; but there is not time to ask what this has to do with the subject. Wilde's dynamo is, of course, to be seen—it always is in such books; and with it the arc lamps of Serrin, Archereau, and Browning. What shall all these things have their decent burial? Electro-motors are taken in on the way, though they have little to do with electric lighting; and we are introduced to a "law" of the electro-motor which, to us, is quite new, namely, that "when the magnetic saturation-point of the iron is reached the increase in efficiency in the machine is not proportional to the increase in current." There is no mention of the discoverer of this law; and the negative form which it assumes is a little discouraging, but still, as Carlyle would say, it is "significant of much."

Berechnung Elektrischer Maschinen. By ERNST H. GEE. (Oldenbourg: Munich.)

This handbook, which has now reached its second edition, deals with the principles underlying the electrical design of dynamos in a manner at once fresh and interesting, which is described by its author as an amplification of the universally used Hopkinson method. This latter only enables the designer to fix the winding of the machine, after assuming the magnetic circuit, to a degree of accuracy greater than is practically necessary; while the author's method goes a step further back and assumes first the number of poles, and from this determines the output per pole, and thence the space required for winding and the volume of iron. Assuming, then, a relation between the construction of inducing and induced magnets the winding and volume of iron are determined, and hence the whole machine. These principles are elucidated in a short introductory chapter of fourteen pages, and the rest of the small volume is devoted to concrete examples of every variety of machine for both direct and alternating currents, and also for transformers. The work is one which would be of value to students of dynamo design, and affords an interesting example of the German practice, which, as is well known, differs so widely from that which finds favour in this country.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 262.)

Some of the methods of preparing filaments will now be described. In spite of all the work that has been done by experimenters during the last ten or fifteen years with a view to providing something new and better, it remains a fact that the original process of Swan's, that of parchmentising cotton thread by sulphuric acid, remains to this day one of the best, if not the best and most easily worked of any. It will, therefore, be described first.

The raw material in Swan's process is pure cotton loosely spun into a thread, such as is sold for knitting. It is usual

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of re-publication reserved.

Digitized by Google

in the first instance, to clean the thread by boiling it in soda or ammonia, to take out any grease which may be present in it and which would prevent the sulphuric acid from acting on those parts which would be thereby protected. It must, however, be thoroughly washed afterwards, in order to remove all traces of the alkali, and then dried.

It is, after all, an open question if the above process of boiling in alkali does any good, provided that the cotton is as clean as it can be obtained in the first instance, for in spite of the process, there are often found to be places in the thread upon which the acid will not act, or rather upon which it will not act in the time allowed. Sometimes these places are very small, and can only be seen by examining the parchmentised thread very closely, while at other times they will extend for several inches along the thread, and occur at short intervals. No satisfactory explanation of these acid-proof, or partially acid-proof, sections has yet been given, or, at any rate, no satisfactory remedy has been proposed.

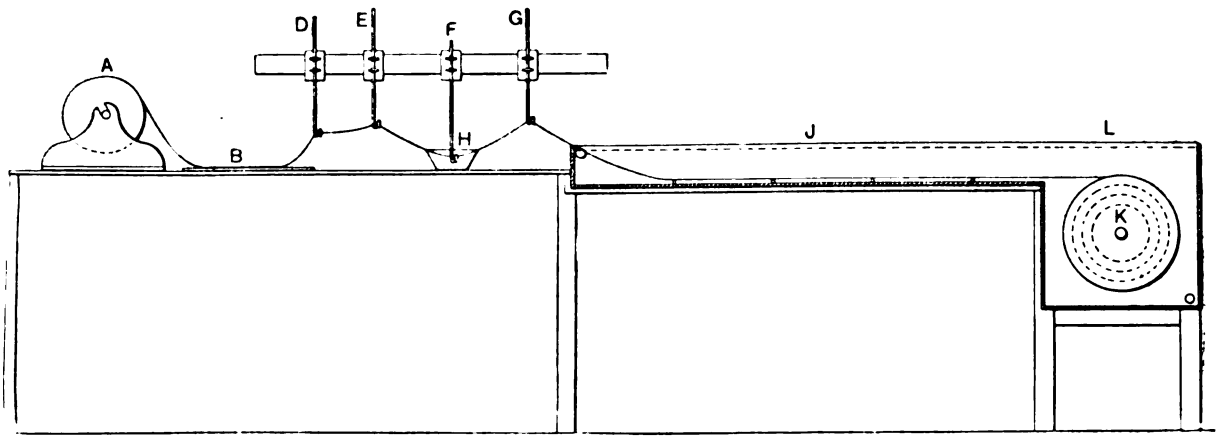

FIG. 1.

When dry, the cotton thread is wound on a drum, and from the drum it is unwound and drawn through a dish of sulphuric acid of the required strength, whence it is drawn into water and wound on another drum which is preferably wholly under the water.

Fig. 1 shows an arrangement which the author has found to work very well. At the left-hand end is seen the drum A, upon which the thread is wound in the first instance. K is the drum on which the thread is ultimately wound and which draws it along. The thread has to be guided in its passage from one drum to the other, so as to pass for the right length of time through the acid and then into the water. It must be remembered, that the action of the acid continues from the moment when the thread enters the acid until it enters the water, though the thread is only actually under the acid in the dish for a short time, after which it passes through the air until it reaches the water.

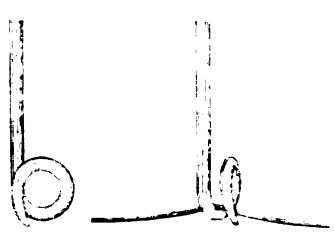

FIG. 2.

In order to guide the thread with the minimum of friction, glass rods with an open loop formed at the end may be used, (Fig. 2), the thread passing through the loop. The advantage of this form is that the thread may be put into the loop while in motion without having to thread the end through first. A number of blocks, D, E, F, G, Fig. 1, are mounted on a bar about eighteen inches above the bench, each capable of sliding lengthwise along the bar. To each block one of the glass guide-rods is attached so that it may slide up or down and be held at the required height by a clamp. Between the left-hand drum A, and the first guide-rod D, a sheet of glass B, is laid on the bench. H is a dish containing the acid. J is a lead-lined trough of some six feet in length, terminating in a tank L, which contains the winding drum K, driven from overhead by a band.

In starting the apparatus, sufficient thread is wound off the drum A, so that the end will reach to K. More thread is then wound off A, and laid zig-zag fashion across the glass-plate B. The first length of thread is then dropped into the glass guide-rods and the end is looped on to a projection on the edge of the drum K as it revolves. The thread is, therefore, wound on to K and drawn along from off the plate B. One of the guide-rods, say F, is now lowered so that it depresses the thread below the surface of the acid in the dish H. On emerging from the acid, the thread passes up through the guide G, and then drops by its own weight into the water in the trough J. The object of the trough J is that the thread may be examined easily in order to see if it is receiving the proper amount of treatment. It can be best examined while passing along this trough, as it is readily seen in the water against the lead lining of the trough. On coming out of the acid dish, the thread has a transparent and bright appearance, like a string of jelly. When it enters the water it is immediately changed from the transparent to a semi-opaque condition. It is at this point, after entering the water, that it must be constantly watched to see if it is receiving the proper amount of treatment. If it is not being done sufficiently, it will have a core of unconverted cotton running through it continuously or in patches. If it is receiving the proper amount of treatment, it will appear as a semi-opaque homogeneous thread. On the other hand, if the treatment is too long, the thread will probably break. It is, therefore, necessary at starting to give it less than the proper amount of treatment. The acid dish can then be moved gradually further back, so that the thread has a longer distance to travel from the acid to the water. If more treatment than can be given by this means is required, the speed of the drum K must be reduced. When the apparatus is adjusted, the acid dish, the edge of which is ground level, is covered by pieces of sheet-glass so that the acid is not exposed to the air, only a small opening being left just where the thread enters and leaves. As the thread is drawn along, it is of course taken up off the glass plate, and the attendant must take care to have more thread wound off the drum and laid across the glass plate before the last lot is used up, or a breakage will occur. Another plan is to drive the drum A as well as K by power. The thread is then unwound from A as it is wanted. The former method, however, gives less trouble. By the method of laying out the thread in zigzag rows on the glass plate, the attendant has sufficient time to examine the thread as it passes along the trough, and keep the apparatus working properly. A sheet of glass is required, because the fine fibres of the loosely-spun thread are apt to catch if laid out on an ordinary wooden bench, unless it is of hard polished wood. The slight momentary strain produced in this way is often sufficient to cause a breakage. In order to still further reduce the strain, porcelain or glass pulleys

Digitized by Google

driven at the proper speed may be used instead of the glass guide-rods (Fig. 2). The latter, however, are much simpler, and answer the purpose quite well. One girl can easily work the apparatus. There is a supply of water at the bottom of the tank L, with an overflow at the end of the trough J. Fresh water is thus always coming in by the drum, and passing along the trough. The strong acid carried into the water by the thread is thus washed out without getting far along the trough.

The strength of the acid is an important consideration. A specific gravity of 1·64, as recommended by Mr. Swinburne, works very well. This is a little stronger than that mentioned by Swan in his patent. The temperature at which it is used should be from 60° to 70°F. A large quantity of acid should be made up to the required strength and drawn off in small quantities as required.

It is a curious fact that the finer threads are more easily worked than the larger, and are less liable to breakage. A much shorter immersion in the acid is required, as a rule, for the larger sizes of thread than the smaller. The speed at which the thread must travel is from twelve to twenty-four feet per minute, and the length of thread under acid (from where it enters the acid to where it enters the water) will be from twelve to thirty-six inches. The actual time, therefore, during which the acid is acting on the thread will be from two and a-half to fifteen seconds, according to the quality and size of the thread and the tightness to which it is spun.

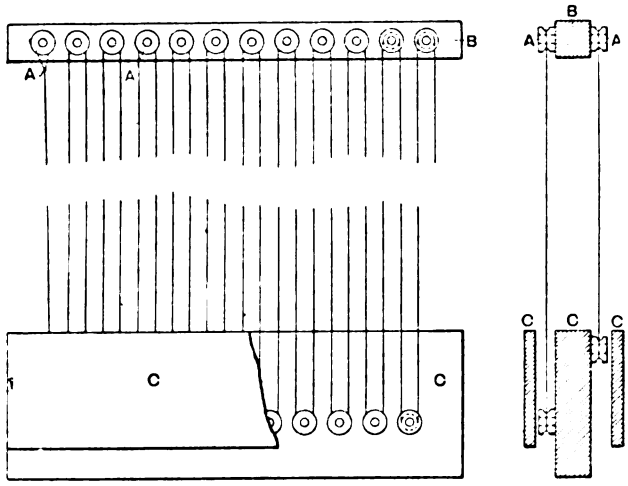

Fig. 3.

Guide-rods may be arranged in front of the winding-drum K, so as to gradually move the thread along the length of the drum and ensure it winding evenly. This, again, is an unnecessary refinement. A glass rod fixed to a piece of wood, which can be laid across the trough and moved by hand every now and again, is quite sufficient. It does not matter if the thread is wound on the drum in several layers, as it is easily wound off afterwards, and the washing of several layers does not take much longer than a single one. If only one layer is wound on the drum, the number of drums and washing tanks is multiplied, and time is lost in changing the drums more frequently. The drum K may be made with a wood spindle and ends, and covered with copper gauze, which allows of a more rapid and thorough washing of the thread than a solid surface would do. When a drum is filled it is lifted out of the tank L and removed to another tank, in which the thread is further washed by a continual circulation of water. In twelve hours or so all traces of acid will have been removed from the thread, which is then ready for drying.

The parchmentised thread quickly dries on exposure to dry air, and in doing so it hardens and contracts. It is consequently necessary to take it off the drums on which it has been washed and hang it up in order that it may dry evenly and straight. A convenient method of drying is shown in the accompanying sketch, Fig. 3.

A number of bars of wood are fixed parallel to each other, eight or nine feet above the floor of the drying-room and about two feet apart. On each side of these bars, B, are secured a number of porcelain insulators, A A, at intervals of a little less than their own diameter, about two inches. Immediately below the bars is fixed on the floor a framework consisting of three boards set up edgewise, the two outer ones not reaching to the floor by two inches or so, except at the ends, the space between the two outer boards and the centre one being a little more than the width of the insulators. In order to dry the parchmentised thread, the drum on which it is wound is taken out of the washing tank and set in a stand so that it can be turned round. One operative takes the end of the thread and ties a loop on it, and standing on a pair of steps, hangs the loop on the farthest insulator. A second girl unwinds the drum, and a third one takes the thread as it comes off and hands it to the first one, who hangs it again over the second insulator, while she (No. 2) proceeds to hang another insulator in the loop thus formed and lower it between the boards, the length of the loop being so adjusted that the

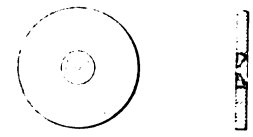

Fig. 4.

insulator hangs at the bottom of the outside board. This operation is continued until the whole length of the parchmentised thread is hung up, with a weight on every loop to keep it stretched. As the thread dries it contracts and raises the weights hanging in the loops to nearly the top of the boards. When dry the thread has become again more transparent and has somewhat the appearance of catgut. It is then taken down and wound on a reel, and is ready for the next process of cutting to size. The boards, C C C, are for the purpose of preventing the weights from falling off the thread and the loop from twisting on itself. When taking the thread down the weights are easily shaken off. The outside boards, C C, are fixed above the ground so that the weights can be got out easily if they fall between the boards. This method of drying insures that the thread all along gets the same tension. For thick thread it may be necessary to use heavier weights than for the smaller sizes.

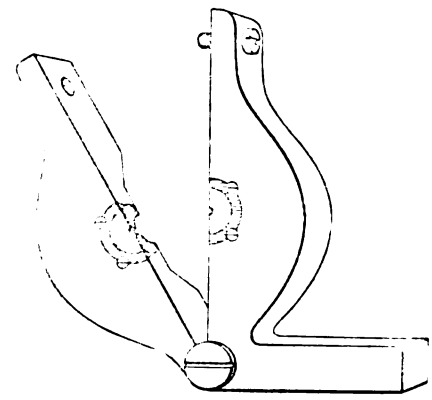

Fig. 5.

Another method is to have porcelain pulleys instead of the insulators, and the bottom ones fixed as well as the top. The thread is then wound up and down, and one weight only hung upon the end. This method, however, puts on a varying strain owing to the friction in the pulleys, and some lengths will be pulled tighter than the others. Besides, the thread, as soon as it begins to get dry, stiffens, and will not readily pass over the pulleys. In the first method it will be seen that the thread is not required to move past the pulleys as it contracts.

The chemical action of this parchmentising process is remarkable, inasmuch as the parchmentised thread appears to retain the same composition as the thread ($C_6H_{10}O_5$), from which it is made, though in appearance it is an absolutely different substance. There is, however, an increase in weight equal of about 8 per cent. The substance so produced is

Digitized by Google

called amyloid, and, as will presently be explained, it can be produced by other methods. The amyloid thread produced as above has a rough and uneven surface, and it must be shaved down and made even before it is fit for use. This cutting down is accomplished by pulling the parchmentised thread through sharp-edged draw-plates. As there are often lumps on the thread, it has to be drawn through several sizes of draw-plates in order to remove these lumps before it is passed through the smaller sizes, which will shave it along its whole length. If it is drawn through too small a plate at first, it will break when the thick parts reach the draw-plate. Steel draw-plates can be used, but the cutting edge will very soon become blunt. Jewelled plates are therefore generally used, and even the hard stones used in these frequently require sharpening. The size of thread parchmentised is proportioned as nearly as possible to the size necessary for the particular filaments required, so that there shall be no more cutting down than is necessary for obtaining even filaments.

The draw-plates used for the larger sizes of thread may be similar to the ordinary jewelled wire draw-plates, but with a sharp-cutting edge, Fig. 4. For the smaller sizes, however, below about twenty mils, it is necessary to use split draw-plates, owing to the difficulty of threading them. Fig. 5 is an illustration of a split draw-plate. The ends of the larger sizes of thread can be easily pointed with a knife, and pushed through the circular draw-plates, and pulled through at first with tweezers. It is, however, very difficult to do this with the smaller sizes, and it is, therefore, better to use the split form. The circular form is used whenever possible, as it costs very much less than the split one. The thread must be drawn through the plates as regularly as possible, and for this reason the plate is fixed upright on a bench, and twelve inches or so behind it there is a wooden drum turned by power. A couple of feet or so of the thread is pulled through the die by hand and then turned once or twice round the drum, which then does all the pulling in a steady and even manner, so that the thread is much less likely to break than if it is drawn by hand. A guide should be fixed both in front and behind the draw-plate, and in line with the hole, so that the thread is always drawn through perfectly at right angles to the front surface which contains the cutting edge. If the thread is not drawn through straight it will be cut unevenly and of an oval section instead of circular. When the jewel becomes dull, and will no longer cut properly, it can be sharpened and made as good as new again, though it will by the process be made larger in the hole, and will only serve for a larger size of thread than before. The thread must be passed through several sizes of plate each a little smaller than the last. The amount cut off by each plate should not be more than about 5 per cent. of the diameter of the thread, except, perhaps, at starting, when lumps only are being cut down. This process of cutting down when properly carried out gives the thread a smooth, polished surface, and makes it perfectly circular. It is then ready for being blocked for carbonisation.

(To be continued.)

THE ELECTROLYSIS OF STEAM.*

BY J. J. THOMSON, M.A., F.R.S.

It is well known that steam is split up into hydrogen and oxygen when an electric discharge passes through it. A very careful examination of the laws of this phenomenon was made more than 30 years ago by Perrot ;† as his results are very remarkable, and seem to be not at all well known, I will describe, as briefly as possible, his apparatus, and the results he obtained with it. The spark passed between two platinum wires sealed into glass tubes, which they did not touch, except at the places where they were sealed ; the open ends of these tubes were about 2mm. apart, and the wires terminated inside the tubes at a distance of about 2mm. from the ends. The other ends of these tubes were inserted under test tubes in which the gases, which passed up the tubes, were collected. The air was exhausted from the steam vessel, and the water vapour, through which the discharge passed, was obtained by heating the water in the vessel ; special precautions were taken to free this water from any dissolved gas. The stream of vapour arising from this water drove up the tubes the gases produced by the passage of the spark ; part of these gases was produced along the length of the spark. Part of the gases so collected have been decomposed by causes which would not be affected by reversing the electrical conditions of the electrodes, *e.g.*, by such causes as the heat produced by the sparks. We should not expect to find any simple relation between the amount of decompositions from these causes and the quantity of electricity which had passed through the gas. The hydrogen and oxygen produced by such causes would, however, be driven up the tube in chemically equivalent proportions, and could therefore be eliminated by sending a spark through these gases, when they would recombine and form water.

When the sparking had ceased, the gases which had collected in the test tubes were analysed ; in the first place they were exploded by sending a strong spark through them ; this at once got rid of the hydrogen and oxygen which existed in chemically equivalent proportions, and thus got rid of the gas produced by heat, &c., along the length of the spark. After the explosion, the gases left in the tubes were the hydrogen or oxygen in excess, together with a small quantity of nitrogen, due to a little air which had leaked into the vessel in the course of the experiments, or which had been absorbed by the water. The results of these analyses showed that there was always an excess of oxygen in the test tube in connection with the positive electrode, and an excess of hydrogen in the test tube connected with the negative electrode, and, also, that the amounts of oxygen and hydrogen in the respective tubes were very nearly chemically equivalent to the amount of copper deposited from a solution of copper sulphate in a voltameter placed in series with the discharge tube. In Perrot's experiments the excess of hydrogen appears at the negative electrode, the excess of oxygen at the positive ; Ludeking* confirmed this result.

As these results bear very closely on the method by which the discharge passes through gases, and seem to have special reference to a view which I have long held, that the discharge through gases is accompanied by chemical changes analogous to those which take place in electrolytes conveying currents, I was anxious to repeat and, if possible, extend them.

The form of apparatus which I now use, though similar in its main features to that used by Perrot, differs from it in some respects. Before describing the apparatus in detail, I will indicate the chief points of difference between it and Perrot's.

One source of doubt in Perrot's experiment seemed to me to arise from the proximity of the tubes surrounding the electrodes to the surface of the water. These tubes were narrow, and, if they got damp, the sparks, instead of passing directly through the steam, might conceivably have run from one platinum electrode to the film of moisture on the adjacent tube, then through the steam to the film of moisture on the other tube, and thence to the other electrode. If anything of this kind happened, it might be urged that, since the discharge passed through water in its passage from one terminal to the other, some of the gases collected in the tubes might have been due to the decomposition of the water and not to that of the steam. To overcome this objection, I have (1) removed the terminals to a very much greater distance from the surface of the water, and placed them in a region surrounded by a ring burner, by means of which the steam can be heated to a temperature of 140° or 150° C. ; (2) I have got rid of the narrow tubes surrounding the electrodes altogether by making the tubes through which the steam escapes partly of metal, and using the metallic parts of these tubes as the electrodes.

Though I prefer this method of arranging the electrodes as being somewhat more convenient than Perrot's form of the experiment, in which the electrodes were wires surrounded by glass tubes, I have repeated the experiments described below, using wire electrodes ; the results, however, were precisely the same as those obtained when the tubular electrodes were used. One great advantage of these tubular electrodes is that the quantity of metal in them is large enough to keep them quite cool during the discharge ; while, when wire electrodes are used the end of the negative terminal becomes red hot if any considerable current passes through the steam.

Instead of following Perrot's plan of removing the mixed gases from the collecting tubes, and then exploding them in a different vessel, I have collected the gases on their escape from the discharge tube in graduated eudiometers provided with platinum terminals by means of which the mixed gases were exploded *in situ* at short intervals during the course of the experiments. This plan avoids the trouble, waste of time, and risk of error incurred in moving the mixed gases from the collecting tube to the eudiometer. Its greatest advantage, however, is that it enables us to see with very little delay at which terminals the excesses of hydrogen and oxygen are appearing.

Description of the Apparatus.

I will now pass on to describe the form of apparatus which, after many trials, was found to be the most convenient. This is represented in Fig. 1. H is a glass bulb, 1·5 to 2 litres in volume, containing the water which supplies the steam. A tube, L, about 0·75cm. in diameter and 35cm. long, is joined on to this. In many cases this was *fused* directly on to the bulb; I do think, however, that this is necessary, and I have found no ill-effects arise from making this connection by placing a rubber stopper in the prolongation of the bulb, and pushing the tube L through a hole in this stopper, care being taken to push the tube right through the hole.

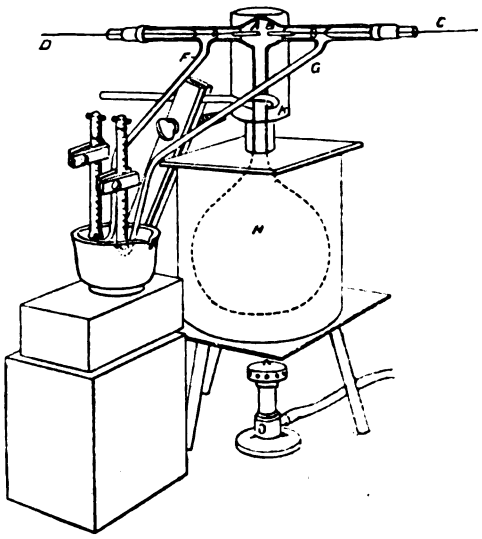

FIG. 1.

The top of the tube L is fused on to the horizontal discharge tube C D; this tube is blown out into a bulb in the region where the sparks pass, so that when long sparks are used they may not fly to the sides of the tube. The top of the tube L, near its junction with C D, is encircled by a ring burner K, and this part of the tube is surrounded by an asbestos case; by these means the steam may be superheated to a temperature of 140° to 150°C. The details of the electrodes between which the sparks pass are shown in Fig. 2. For the metal parts *a b* it is necessary to use some metal which is not oxidised by the steam, as a very small amount of oxidation would be sufficient to render the results nugatory. I have used as the electrodes, (*a*) brass tubes thickly coated with gold with their sparking ends carefully rounded off, or (*b*) tubes made by winding thick platinum wire up into a coil. These tubes are placed in pieces of glass tubing, *e e*, to hold them in position. To faciliate the expulsion of air from the apparatus, it is desirable that the metal tubes should not fit so tightly into the glass ones as

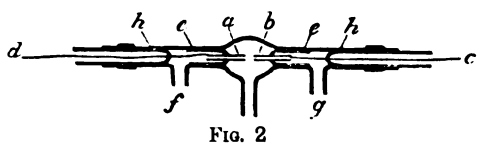

FIG. 2

to prevent the steam from passing the two. If they fit too tightly to allow this, air is apt to lodge between the metal and glass tubes, and if this gets driven out into the delivery tubes F G (Fig. 1) when the sparks pass, it will vitiate the experiment. The glass tubes *e e* stop short of the places *f g* where the delivery tubes join the discharge tube. The discharge tube is closed at the ends by two pieces of tube, *h h*, which have their ends inside the tube fused up; wires connected to the electrodes *c d* are fused through the closed ends of these tubes. It is desirable that the closed ends of the tubes *h h* should come up as close as possible to the exits *f g*, as air is very apt to remain in the tube if there are any places through which the steam does not rush. The tubes *h h* may either be fused on to the spark tube or fastened to it by rubber tubing. The delivery tubes F G (Fig. 1) are fused on to the discharge tube at *f g* (Fig. 2). These tubes are about 5cm. in diameter and terminate in narrow openings. It is essential that the steam and the mixed gases should escape through the tubes F G at approximately the same rate; to ensure this, the narrow extremities of these tubes should be equal both in length and width. This was attained by drawing out a piece of tubing which was originally of the same diameter as F G, and then cutting it at the middle of the narrow part; the two halves were then either fused or fastened by rubber tubing to F G. The narrow ends of F G are turned up and placed under mercury in the vessel M (Fig. 1). Over these ends, graduated eudiometer tubes are placed; these are filled with mercury at the beginning of the experiment, but the mercury soon gets displaced by the water produced by the condensation of the steam rushing through the tubes.

The heat produced by this condensation serves a useful purpose; it raises the temperature of the water in the eudiometer tubes over which the gases are collected to over 80° C., and thus, since hot water absorbs oxygen, but not hydrogen much less readily than cold, diminishes the disturbing effect due to the greater absorption of the oxygen than of the hydrogen by the water over which the gases are collected.

Precautions which it is necessary to take to ensure Correct Results.

To get rid of the air dissolved in the water I found no plan so efficacious as prolonged boiling. In the earlier experiments, in addition to the boiling, I tried to absorb the oxygen by mixing oxidising agents with the water; finally, however, I dispensed with these and trusted entirely to the boiling to remove the air. The distilled water was boiled vigorously for six or seven hours with the ends of the tubes F G open to the atmosphere. The eudiometer tubes filled with mercury were then placed over the ends of the delivery tubes F G, so that if any air were mixed with the steam it would be collected in these tubes. The steam was then allowed to run into the eudiometer tubes for about an hour, when the tubes were examined to see if they contained air. If any air was observed the eudiometer tubes were removed and vigorous boiling maintained until, on repeating the experiment, the air was found to have disappeared.

Method of Producing the Sparks.

The sparks were produced by means of a large induction coil, which would give sparks about 5cm. long when the current from five large storage cells, which was the usual battery power employed, was sent through it. The break used was, generally, the ordinary electromagnetic break supplied with these coils, but in some experiments a slow mercury break was employed. I found that, as I believe is the case with all induction coils, the condenser supplied with it had not nearly enough capacity to enable the coil to give out its maximum current. When I added to this condenser a large paraffin paper one, with a capacity of about 6 microfarads, the current from the coil was increased more than twenty times, and I found no difficulty in getting from 4 to 6 c.c. of hydrogen liberated per hour in the water voltameter in series with the discharge tube. In order to measure the quantity of electricity which passes through the spark tube, a well-insulated water voltameter was placed in series with it, and the quantity of hydrogen liberated in this voltameter observed. The gases liberated in this voltameter were repeatedly tested, in order to see whether there was any mixing up of the hydrogen and oxygen in the collecting tubes over its electrodes. Such admixture seemed possible, as the electromotive force produced when the circuit is "made" is in the opposite direction to that produced when it is broken. The test consisted in vigorously sparking through the gases collected in the voltameter, but no contraction occurred. As, however, it is very difficult to get a mixture of hydrogen and oxygen to explode if the hydrogen is greatly in excess, I added to the hydrogen in the voltameter enough oxygen to cause an explosion; the contraction in this case corresponded to the oxygen added, showing that there was no oxygen originally present. We may therefore conclude that the current sent through the secondary circuit on "making" the coil is in this case too small, in comparison with that produced on "breaking" the circuit, for its effects to be appreciable.

Method of Making the Experiments.

After it had been ascertained that all the air had been expelled from the vessel the eudiometer tubes were filled with mercury and placed over the ends of the delivery tubes, and the spark tube connected up with the coil. The next step was to see if the rates of flow through the delivery tubes were approximately equal. This was done by turning on the coil and collecting the mixed gases in the eudiometer tubes; if the volume of these gases in the two tubes was not the same, the apparatus had to be readjusted. When the rates of flow through the two tubes were the same the mixed gases were emptied out of the collecting tubes, which were refilled with mercury; the water voltameter was placed in series with the steam tube, and the coil again set in action. The steam which came up the collecting tubes condensed into hot water, which soon displaced the mercury; the mixed gases collected over this hot water, and were exploded at short intervals of time by sparks from a small Wimshurst machine. The gases did not disappear entirely when the sparks passed; a small fraction of the volume remained over after each explosion, and the volume which remained was greater in one tube than in the other.

The residual gas which had the largest volume was found on analysis to be hydrogen; the other was oxygen. Thus, by comparing the volumes of the residual gases in the two tubes it could

Digitized by Google

readily be ascertained next to which electrodes the excesses of hydrogen and oxygen were appearing.

When a sufficient quantity of the residual gas had been collected, which generally happened when the sparks had been passing for an hour or an hour and a-half, a considerable volume of the mixed gases was allowed to accumulate, so as to make sure of an explosion when the spark from a Wimshurst passed through them. The coil was then stopped and the mixed gases exploded, and the quantity of hydrogen in the water voltameter determined. The residual gases in the collecting tubes were then analysed; the first step was to cool these gases, which while the steam had been rushing into the tubes had been at a temperature of more than 80°C., down to the temperature of the room. After this had been done the nature of these gases was determined by adding known volumes of oxygen and hydrogen, prepared electrolytically from water and observing the contraction which took place when a spark passed; the addition of the hydrogen or the oxygen, as the case might be, was continued until no further contraction took place on sparking.

The result of these analyses was that when the sparks were not too long the residual gas in one tube was found to be pure hydrogen, that in the other pure oxygen; if any other gases were present their volume was too small to be determined by my analysis. This result was only attained after considerable experience with the experiments and with the precautions necessary to obtain correct results; in the earlier experiments there was always a considerable quantity of some other gas (which, I suppose, was nitrogen) present.

When the sparks passing through the steam were very long I never succeeded in getting rid of this nitrogen; indeed, in some cases it amounted to more than 30 per cent. of the oxygen. I am not sure what the source of this nitrogen is; it may have been absorbed by the electrodes and given out when the sparks pass, or it may have come from the walls of the discharge tube, as these long sparks have a tendency to occasionally jump to the walls, and when they do so they may liberate air which would otherwise adhere to the glass.

Results.

The results obtained by the preceding method varied greatly in their character with the length of the spark; I shall therefore consider them under the heads "short sparks," "medium sparks," and "long sparks."

The lengths at which a spark changes from "short" to "medium" and then again to "long," depends on the intensity of the current passing through the steam, and therefore upon the size of the induction coil and the battery power used to drive it. The limits of "short," "medium," and "long sparks" given below must therefore be understood to have reference to the particular coil and current used in these experiments. With a larger coil and current these limits would expand; with a smaller one they would contract.

(To be continued.)

ARC LAMPS AND INCANDESCENT GAS BURNERS.*

BY DR. W. WEDDING.

Many recent researches have had for their object the investigation of the "incandescent gas lamp," which has of late years attained to such wide use, and the investigators have generally not confined themselves to this form of illuminant, but have also instituted comparisons with the electric arc. To two of these researches the author calls attention: that of Herr v. Oechelhäuser and that of Prof. Heim. The former compared incandescent gas lamps with both 16 and 50 candle incandescent electric lamps, in order to compare two

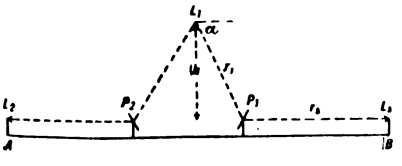

Fig. 1.

lamps of approximately equal candle power; but this can be better done by utilising the small arc lamps now made, which take currents of from one ampere upwards, and this method was adopted by Prof. Heim; but the author considers that these researches suffer from incompleteness. In a practical research it is no good measuring horizontal or any other illumination if the source of light be not provided with the usual shades or globes, since the latter entirely alter this distribution; and in detailing experiments on these practical points the author believes himself not to be traversing well-trodden ground.

* Abstract from *Elektrotechnische Zeitschrift*, No. 21, May 26, 1893.

The experiments were conducted as follows:—The illumination at various angles to the horizontal plane is measured as shown in Fig. 1, where L_1 is the lamp under investigation, A B the photometer bench, and L_2 and L_3 are lamps fixed at the height of

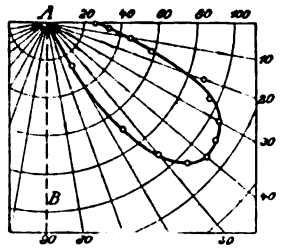

Fig. 2.

the two photometers P_1 and P_2. The two lamps are brought to the same brightness, and their strength determined with the amyl-acetate lamp, and L_1 is then started; when fairly burnt up,

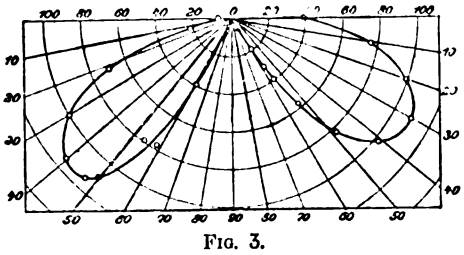

Fig. 3.

the height h over the axes of the photometers is so altered as to determine at every 10deg. inclination the candle-power, which is given by the formula $L_1 = L_2 r_1^2/r_2^2$ if the angles of incidence be

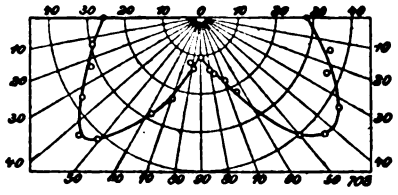

Fig. 4.

equal. The distribution above the horizontal plane is determined by cutting away the bench and sinking the lamp L_1; and, of course, every care is taken to burn the lamps in the best and most equable manner.

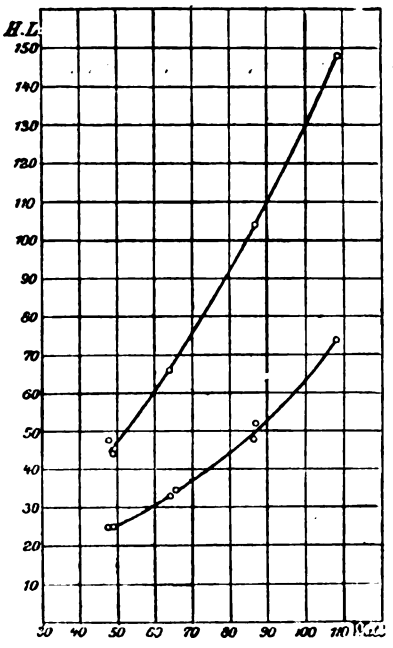

Fig. 5.

Two arc lamps were tried, one made by the Allgemeine Elektricitäts-Gesellschaft and the other by Siemens and Halske, with currents of 1·5-3 ampere. The former has a small opal globe

Digitized by Google

made to sink with the burning away of the carbons, so that the arc always remains in its centre, and the whole lower part of the lamp is surrounded by another glass globe transparent and of pear-shape;

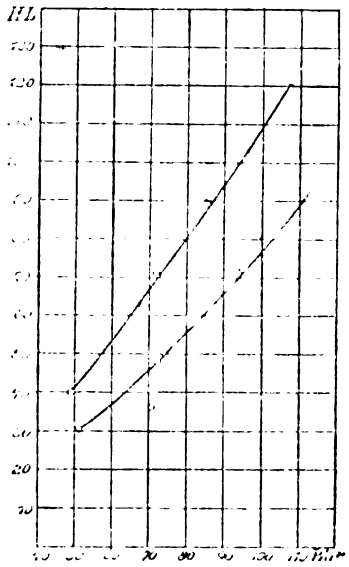

Fig. 6.

while the latter has only one glass globe of about the same dimensions as the transparent globe of the former; both have 500 ohm shunts. The first of these has the curve shown in Fig. 2, which

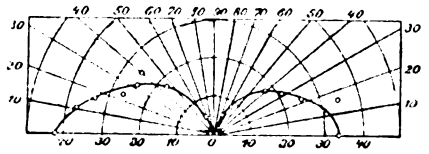

Fig. 7.

is the mean of the readings in two opposite directions for every angle. The actual observations are shown in Fig. 3. To obtain the mean spherical intensity, suppose the curve to rotate round a

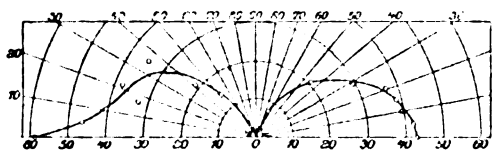

Fig. 8.

vertical axis A B, calculate the volume of the solid so described, arriving thus at the total light emitted below the horizontal; spread this on the surface of a hemisphere of radius 1, and we get

Fig. 9.

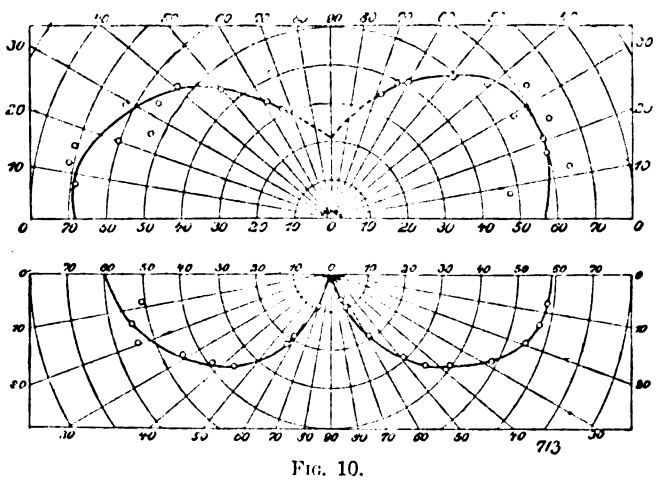

Fig. 10.

a number which we call the mean spherical intensity $i_m = V/F$, where V is the volume of the solid and F the surface on which the light is spread. Applying this to the above observations, we have $i_m = 66$ Hefner-light units, and as the watts spent are $= 64{\cdot}2$, we have for every watt a mean intensity of 1·03 Hefner unit.

These figures are *without shades*. With shades we have the curve shown in Fig. 4, the mean spherical intensity below the horizontal being 33 Hefner units, or 0·514 unit per watt. The next figure

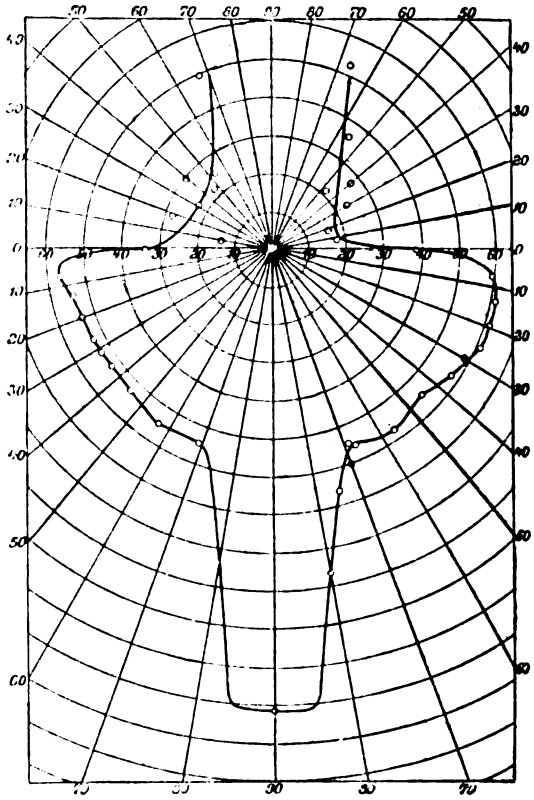

Fig. 11.

(Fig. 5) shows the mean spherical intensity for different values of watts, keeping the pressure constant and altering the current, the upper curve without shade, the lower one with; and the curve shows that for all values of the light the globe absorbs about 50 per cent. The same experiment with the Siemens and Halske lamp gives the results shown in Fig. 6, where it will be seen that the amount absorbed by the shade varies from 25 to 33 per cent., due to the fact that with larger currents a greater proportion of the light is sent upwards, as shown in Figs. 7 and 8, which give the upper distribution for 2·5 and 3 amperes respectively.

The gas glow-light was next investigated, a good burner, without globe, being supplied with gas at 35mm. (water) pressure, and the

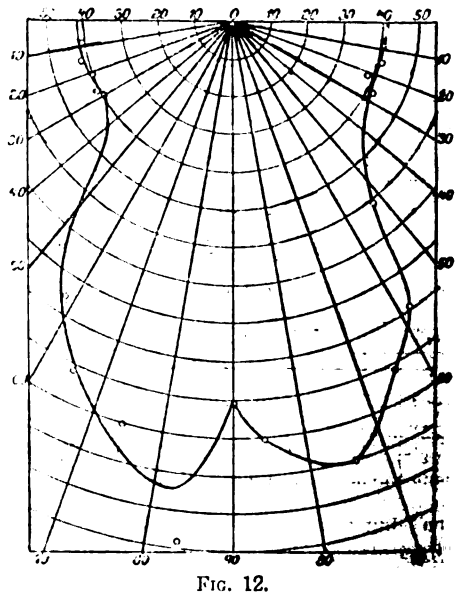

Fig. 12.

curves in a vertical plane are shown in the next two figures (9 and 10), which do not quite fit, having been taken on different days. The figures give a mean spherical intensity of 0·392 Hefner

Digitized by Google

unit below and 0·503 above per litre of gas per hour* (1 litre = 0·035 cubic ft.), or 1·39 and 1·78 unit respectively per 100 cubic ft. It is thus seen that, owing to the distribution, an arc lamp with a shade and a gas glow lamp without one are equally exceptional. The irregularities in the curves are due to those in the incandescent material.

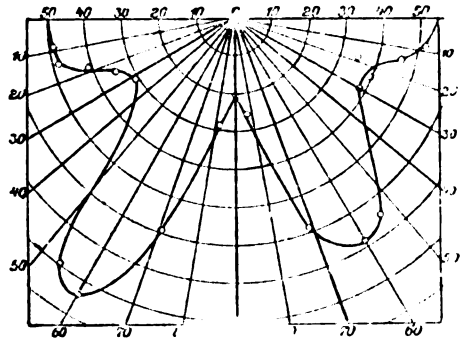

Fig. 13.

The shaded gas lamp was next tried, Fig. 11 referring to one with the usual white china reflector and white shade for the eyes, Fig. 12 to an opal globe. Figs. 13 and 14 relate to a bell shade and a matt globe respectively. The following considerations show that the figures obtained for the spherical intensity, namely,

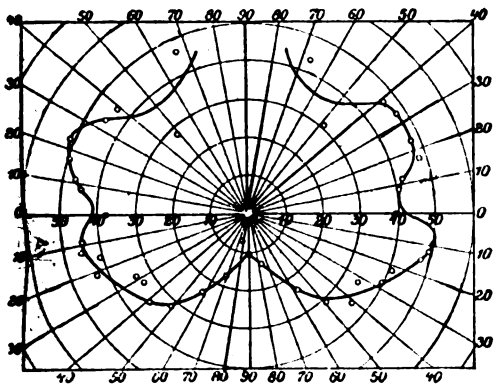

Fig. 14.

0·523 and 0·505 per litre per hour respectively (1·85 and 1·79 units per 100 cubic ft.) are not much use for purposes of comparison. A consumer knows nothing and cares less about mean spherical intensity, what he wants is that his show window or his table should be properly lighted, and he does not mind how this is effected. Consider Fig. 15. The intensity

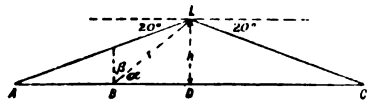

Fig. 15.

of illumination at any point B of the illuminated surface A C is $B = J \cos\beta / r^2$, where r is the distance from the source of light L, J the strength of the light coming in this direction, and β the angle of incidence; and this can be written also $B = J \sin^3 \alpha / h^2$, and from this equation with the help of the curves given the illumination at

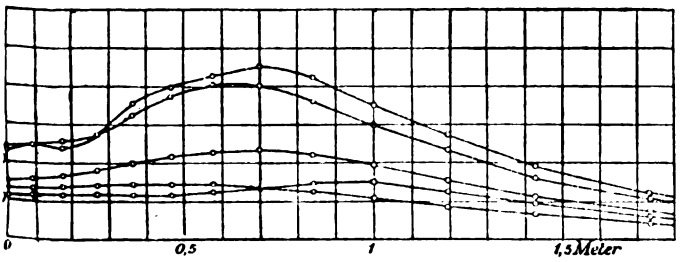

Fig. 16.—Distribution of Light from Siemens and Halske Arc.

every point on the surface can be calculated, as has been done in the curves Figs. 16, 17, 18 for the Siemens and Halske arc, that of the Allgemeine-Elektricitäts-Gesellschaft, and the incandescent gas-burner respectively, with their different shades. It is a very striking feature of these curves that the arc lamp far surpasses the gas burner in uniformity of illumination, a point which is of the utmost importance, since the eye chiefly notices differences of illumination, and not its absolute strength. The average strength is given as before, by the volume of the solid of revolution of the curve surface round the axis of ordinates, and is $i_m = V F$, which

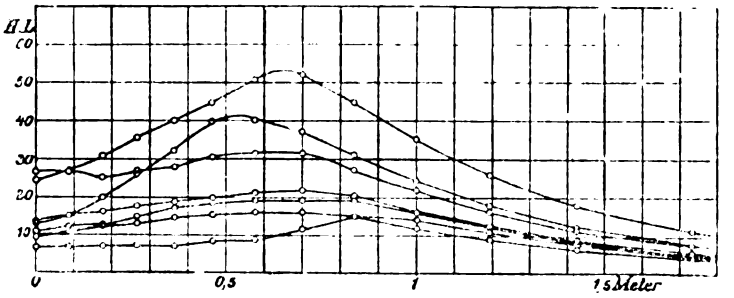

Fig. 17.—Distribution of Light from Allgemeine Gesellschaft.

works out naturally much more in favour of the arc light. To make the comparison of real value, an average of five burners was taken with the following results:—Take the case of a ground-glass globe for each. The gas lamp gives a mean spherical intensity of 0·0378 per litre of gas per hour, and the arc gives $i_m = 0\ 098$ per watt. Assuming that we can get by gas engine and dynamo 1,000 watts for one cubic metre of gas per hour it follows that we can compare the figures for one litre per hour and one watt; and we get, therefore, 2·6 times as much light by using the gas-driven arc lamp as by using a direct consumption of the gas in the Auer burner. In the worst case the arc lamp is better in the ratio

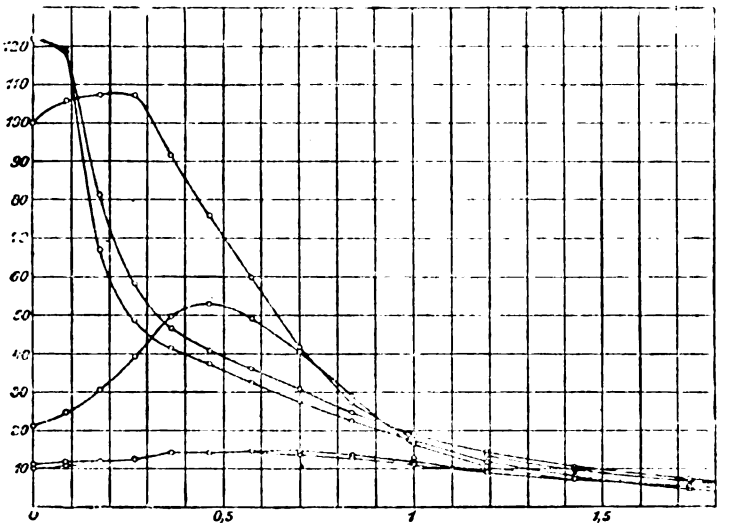

Fig. 18.—Distribution of Light from Incandescent Gas Burner.

1 : 1·3, and in the best it is 1 : 4. These figures apply only to new burners, and the five used were found to fall off 15 per cent. after 100 hours' use. The author leaves to his readers the evaluation of relative cost, which depends too much on local considerations to be of much value when worked out by general methods.

* The author uses throughout the word "litre," apparently meaning "litre per hour"; and the latter expression has been used throughout this abstract.

CORRESPONDENCE.

MEASUREMENT OF INTERNAL RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I quite agree with your Editorial remarks that for practical purposes it is unnecessary to measure the internal resistance of a battery or cell. What is wanted in most cases is to find the maximum current the cell will give for a considerable period of time without much falling off, and the terminal potential difference when giving this current. This can be done by using any form of ammeter or voltmeter, the battery being circuited through a known external resistance. When it is required to determine internal resistance, however, the real internal resist-

Digitized by Google

ance is what is wanted and not its apparent value on the supposition that the electromotive force remains constant, as it is often desirable to know whether falling off in the current given by a cell proceeds from falling off of electromotive force due to polarisation, or increase of true internal resistance due to chemical change in the electrolyte. As a general rule the falling off in power of a cell when used is due to both these, and it is desirable to be able to separate the two effects.

With regard to the Holden cell tests, I did not suppose that this instrument would be used to accurately determine the resistance of a cell, but it seems rather absurd to give the internal resistance to two figures when there may be an error of about 10 per cent. due to inaccuracy *in reading alone*, while adding to this the effect due to polarisation the value obtained for the internal resistance may be 100 per cent. wrong or even more.

Take the reading for the E.C.C. cell as 1·36 instead of 1·38, the probable error is about 15 per cent. due to error in reading alone. I do not quite understand the meaning of your remark, " . . . a delay of a second or so will produce quite as large an error with most primary batteries, due to a change, not only in the readings, but in the quantity to be measured." Now the quantity to be measured is the internal resistance, and this will not appreciably change in a few seconds or even minutes; of course, as I have pointed out, the electromotive force changes in the course of even a fraction of a second. This prevents the value of the internal resistance as calculated being correct, but the real internal resistance remains constant during the time taken to make a test, hence the advisability of employing some method of eliminating the effects of polarisation.—Yours, &c., E. C. RIMINGTON.

THE CONDITIONS DETERMINING CHEMICAL CHANGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice that in your appreciative editorial comments on my note on the conditions determinative of chemical change, speaking of the influence of water, you say, "Its real function may only be to introduce an impurity, possibly an acid, into the sphere of action." Will you, therefore, allow me to point out that this scarcely conveys my meaning. It seems to me that *per se* the acid would have as little effect as water, as, *ex hypothesi*, neither is an electrolyte; but the two together form what I have proposed to term a "composite electrolyte," and an interaction might take place under their conjoint influence which neither alone could condition. In a sense, the water may be said to *introduce* the acid into the sphere of action; but the converse is equally true, and perhaps in many, if not in most, cases, the elements of the water molecule are alone subject to partition. Why a mixture of water and an acid is an electrolyte, and the precise character of the changes attending its electrolysis are *the* questions of the day—not answered by the fashionable ionic dissociation hypothesis, which appears to me to include a host of absurdities, and to be the outcome of extreme "narrow-mindedness."—Yours, &c.,

July 12, 1893. HENRY E. ARMSTRONG.

LEGAL INTELLIGENCE.

Blackie v. Electricity Supply Corporation (Limited).

This case came before Mr. Justice Cave and a special jury on Wednesday and Thursday. It was a claim for damages by Mr. W. G. Blackie, a watch and clock maker, of 379, Strand, on account of interference with his business caused by the working of the defendant Company's machinery in Maiden-lane. The Company denied that their works seriously interfered with the plaintiff's conduct of his business.

The counsel in the case were:—For the plaintiff, Mr. W. R. Bousfield, Q.C., M.P., and Mr. Morton Smith; and for the defendants, Mr. Fletcher Moulton, Q.C., Mr. English Harrison, and Mr. Terrell.

Mr. BLACKIE (the plaintiff) stated that his business of watch and clock maker had been seriously interfered with by the vibration caused to his premises by the defendant Company's electric light machinery. A standard clock in his shop by which he regulated the chronometers and clocks which he either manufactured or repaired had become absolutely of no use to him as he could not now depend upon it, and manufacturing work which he formerly did with the aid of this standard regulator he had now to put out to be done.

On Thursday the Plaintiff was cross-examined, after which THOMAS RUSSELL, his assistant, and others resident in the neighbourhood, gave testimony as to experiencing the vibration.

Mr. MILES WALKER (assistant to Prof. Silvanus Thompson) said that he went on June 8th to plaintiffs' premises. There was a very decided tremour perceptible on the roof, but it was not so strongly perceptible in other parts of the premises. On July 6th also he visited the premises, when the traffic in the Strand was stopped, and then again felt the vibration. He made tests of the number of beats per minute, and found there were 18. On the evening of July 10th he went to the engine room of the defendant's Company and found engines 2, 3, 4, and 5 running at 9 o'clock. He observed a vibration on the defendant's premises similar to that at the plaintiff's premises.

Cross-examined by Mr. MOULTON: He employed, to count the pulsations, an instrument which he constructed specially for the purpose, consisting of the spring from an Ayrton and Perry ammeter, to which was attached a glass fibre as a pointer; this enabled them to see what otherwise could only be felt.

Prof. SILVANUS THOMPSON visited the premises at about seven on the evening of June 1st last. At first the vibration was quite sensible, but ceased after a time, becoming sensible again later. He walked past the electric station and found a sensible vibration in the roadway outside. On June 8th part of the vibration was undoubtedly due to the Strand traffic. He visited the station and found five engines running, four doing work and one running light. On June 23rd he met Dr. Hopkinson at the plaintiff's premises; there was no vibration perceptible in the lower part of the premises, but on the roof the vibration was intermittent, part again being due to the Strand traffic. He went upon that date also to the station and found the total output at 3,200 amperes, which was about half the capacity of the station. So far as he could discover from somewhat incomplete data, engine No. 1, which was now away, had a greater disturbing influence than the others.

Cross-examined by Mr. MOULTON: Running four engines at half load would probably cause less vibration than two at full load. The fact that the vibrations tended at times to accelerate the running of the standard clock and at others to make it lose, might be accounted for by the assumption that the vibrations were of an irregular character.

Mr. FLETCHER MOULTON, Q.C., in opening the case for the defence, remarked that the amount of the output of the station was quite outside the control of the defendants, depending entirely upon the public demand, and it could not be said that there was any arrangement for special occasions, so that the vibration should be less; and when the jury visited the premises (which they did on Monday evening, July 10th) they saw what was the ordinary state of affairs. Mr. Miles Walker had never felt any vibration in the house, and Dr. Thompson only upon one occasion noticed a slight vibration. They had employed a most delicate instrument for the purpose of detecting the vibrations, and such a slight disturbance was not what could be described as a common law nuisance. There must be such a disturbance before the action could succeed, as would substantially interfere with the comfort of people generally in a house, and not with the carrying on of a particular trade. The variation spoken of in the standard clock was of a most minute character—one second in about 50,000. Plaintiff had never regularly used his clock until after the opening of the Company's station, and it was impossible to say what the cause of its irregularity was.

Dr. JOHN HOPKINSON deposed to having frequently visited the plaintiff's shop and being unable to detect any vibration not traceable to street traffic. He could not see that any conclusion could be drawn from a comparison of the register of the load at the central station and of the variations in the regulator clock. Chronometers which, though not precisely like regulators, had a considerable similarity, were used on shipboard, where there was a great deal of vibration, and were found to keep time perfectly.

Cross-examined by Mr. MORTON SMITH: The vibrations perceived upon the night of July 6th, when there was no traffic in the Strand, might have been due to traffic in other adjacent streets; he would not go so far as to say they were probably due to the defendants' machinery. The vibrations which he experienced were not of the regular character spoken of by the plaintiff's witnesses; they were so light that it was almost impossible to allocate them to any definite cause. The variations in the clock were such as might be due to wear and tear of the clock; he did not think they were in any way attributable to the working of the defendants' engines.

Mr. W. H. PATCHELL (the defendant Company's Electrical Engineer) said the engines at the station ran evenly. The same engines were running during the time of the jury's visit as were generally employed. The supply was entirely controlled by the demand of the public. The output in summer time was practically nearly as high as in the winter, but the maximum was not maintained for so long a time. He could trace no connection between the vagaries of the clock and the running of the engines at the station.

Cross-examined: The floors of the engine room were stiffened three months ago, and that lessened the possibility of vibration.

Mr. Edward A. Greening, architect and surveyor; Mr. Spencer Chadwick, Chairman of the defendant Company; the Rev. Fredk. Scrymgeour, Rector of Corpus Christi Church, Maiden-lane; Mr. Gustave Bargen, in the employ of the Tottenham Lager Beer Company, 395, Strand; Mr. Charles Fredk. Lawton, also of the Tottenham Lager Beer Company; and Mr. John Wm. Jones, sub-manager of the firm next door to the plaintiff, all gave evidence as to the absence of vibration.

The Court then adjourned.

The Lighting of Exhibitions.

At Greenock Sheriff Court on Tuesday proof was heard in an action brought by the Gulcher (New) Electric Light and Power Company (Limited), against the promoters of the Royal Marine and Industrial Exhibition, recently held at Greenock, for £53. 12s. 10d. for supplying electric light to defenders' Exhibition. A counter action was raised by the promoters of the Exhibition against the Company for £50 for damages for failure to light sufficiently the football ground in connection with the Exhibition as per agreement and also for several smaller items. In the result a joint minute was lodged by which both actions were taken out of Court on the Exhibition promoters agreeing to pay the Company £32. 10s.

Elmore's French Patent Copper Depositing Company (Limited).

This matter came before Mr. Justice Vaughan Williams for the third time on Saturday last. Three petitions had been presented for the compulsory winding-up of the Company, but when last the case was before the Court application was made on behalf of the official liquidator for the postponement of any order until a contemplated scheme for the realisation of the assets in France had been carried into effect. The petitioning debenture-holders concurred in this application, but counsel appearing on behalf of the unsecured creditors objected. His Lordship suggested an arrangement between the parties, postponing consideration of the matter for the purpose; but on Saturday he made an order for the compulsory winding-up of the Company.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Tenders Invited.—The Tramways Committee of the County Borough of Huddersfield invite tenders for the wiring of and for the supply of electric light fittings for the tramway offices, the plans and specifications for which may be obtained of Mr. A. B. Mountain, borough electrical engineer, Gasworks-street, Huddersfield, to whom sealed tenders must be sent not later than Tuesday, the 25th inst.

——— The Gas and Lighting Committee of the Bolton Corporation are prepared to receive tenders for the supply and erection of alternators and dynamos. Specifications and other information can be had of Mr. H. Rider, borough electrical engineer, and tenders must be sent in to Mr. Alderman Miles, at the Gas Offices, Bolton, by Thursday, August 3rd.

——— The Mayoralty of Jassy (Roumania) will on August 17th (old style) open tenders for the lighting of their town by gas or electricity. Particulars may be obtained from M. A. Solomonesco, Secretary to the Mayoralty, Administrative Office, Jassy.

——— The Carshalton Local Board invite tenders for lighting their district by gas, oil, or other illuminant for 12 months from the 31st inst. Tenders must be in by Wednesday next.

———Tenders are required by the municipality of Dusseldorf, for the supply and erection of a complete electric light and power plant. Tenders must be in by 11 a.m. on September 1st.

Tenders Accepted.—The tender of the International Electric Subway Company (Limited) has been accepted for the supply of the mains for the electric light installation at Portsmouth, for £13,539. Eight tenders were received.

——— The tender of Mr. E. Dewhurst, of Preston, has been accepted for the lighting of the G.U.O.O.F. Central Club at Burnley.

Appointments Vacant.—The City Engineer's Department of the Liverpool Corporation require an electrical engineer to act as electrical inspector. The salary commences at £150 per annum. Further particulars appear in our advertisement columns, and applications must be delivered at the office of the Town Clerk (Mr. George J. Atkinson) not later than 12 o'clock noon on Saturday, the 29th inst.

——— It will be seen by our advertisement columns that the Huddersfield Electric Lighting Committee are prepared to receive applications for the appointment of assistant electrical engineer. Applications are to be sent to Mr. H. Barber, town clerk, not later than Monday, the 24th inst.

Personal.—Mr. Claude W. Hill, manager for Messrs. Paterson and Cooper, asks us to state that his business address is now European Works, Pownall-road, Dalston, N.E., instead of Manchester.

——— Mr. John Lancaster has been appointed general manager of the electric tramways at Blackpool instead of Mr. J. Hesketh, who will require to give his whole time to superintend the new electric lighting system.

Removal Notice.—The offices of the Indestructible Ignition Tube Syndicate (Limited) are removed to more commodious premises at 100c, Queen Victoria-street, London, E.C.

The Holden-D'Arsonval Galvanometer.—With regard to the improvements in the Holden-D'Arsonval Galvanometer, described in our last issue, it should have been stated that these instruments are supplied, as well as made, by Mr. James Pitkin.

Messrs. Paterson and Cooper.—We have received from this firm a copy of their supplementary price list of electrical measuring instruments, together with a table of recent tests made with a view to determine the effect upon them of neighbouring conductors. In no position in which the voltmeter tested could be placed with respect to a lead carrying 1,700 amperes was the effect large enough to be of practical importance; while in the majority of positions, and at distances from the lead exceeding 4in. or 5in., the effect was quite inappreciable.

Gulcher (New) Electric Light and Power Company (Ltd.). We have received a copy of the new price list of the electric plant manufactured by this Company. The list includes dynamos, alternators, transformers, accumulators, motors, arc lamps and accessories, cables, measuring instruments, &c.

Taylor's Patent Flue Cover and Composition for Boilers and Furnaces.—We have received from Mr. G. C. Taylor, of Helsby, near Warrington, a description of his system of covering-in the tops of exterior flues in boiler furnaces. The method consists in the use of a patented compound, which can be readily applied and very quickly removed and replaced, and which possesses very low thermal conductivity. By means of this composition lining, it is possible to open out the roof of the flues and expose them to direct daylight, rendering the operations of inspecting, repairing, or cleaning much safer and more expeditious than in boilers provided with the usual brick lining. A large boiler can be opened, cleaned, re-covered, and the fires started again by two men working for $3\frac{1}{4}$ hours.

Messrs. Felten and Guilleaume.—We have received from this firm a catalogue of their exhibits at the Chicago Exhibition, which comprise electric light, telegraph, telephone, and torpedo cables; mining, marine, and other forms of metal rope, wires, and specimens of joints for cables.

National Telephone Company.—It has been decided to establish a Sports Club in connection with this Company's London staff, to be called the Telephone Athletic Association. An enthusiastic gathering recently took place, under the presidency of Mr. Dane Sinclair, the Company's chief engineer. A provisional executive committee was appointed, with Mr. T. C. Walker as treasurer and Mr. W. E. Dean as secretary.

Accrington.—At the last meeting of the Town Council a question was asked if the Local Government Board had replied to the application for permission to borrow money for the electric light scheme. The Town Clerk, in reply, said that the gas and water question had taken up so much of the time of the Legal and Parliamentary Committee that they had been compelled to postpone the consideration of the electric light question; the Local Government Board had given their sanction to the borrowing of the money for the scheme, but as they had grouped the land, machinery, &c., together, and only offered the Council 25 years for repayment, the Committee did not consider the conditions satisfactory.

Aberystwyth.—At the last meeting of the Town Council Dr. Harries proposed that, as the Council had done nothing under the Provisional Order which they obtained in 1891, the Public Lights Committee be authorised to negotiate with private or other companies, or with individuals, for the lighting of the town by the electric light, which was carried.

Bandon (Ireland).—A notice has been received by the Board of Guardians from the solicitor to the local Electric Light Company, stating that the Company intends to apply for a Provisional Order for the public and private lighting of the town by electricity, and the Board will call a meeting to consider the matter.

Birmingham.—The General Purposes Committee of the City Council have had for some time under consideration the question whether the Corporation should themselves obtain a Provisional Order for the supply of the electric light, and oppose the extension of the Order asked for by the Birmingham Electric Supply Company (Limited). It is understood that the Committee have decided that it would be inadvisable for the Corporation to undertake the supply of electricity, and they will therefore report to the Council in that sense. It would seem that the negotiations mentioned in the "Trade Notes" in *The Electrician* of June 23rd, page 215, as being carried on between the Company and the Corporation have resulted in a mutual understanding.

Digitized by Google

BOGNOR.—The Local Board have been notified that the London and Lancashire Electric and General Engineering Company (Limited) intend applying to the Board of Trade for a Provisional Order, authorising them to supply electricity in the town.

BOLTON.—At the last meeting of the Corporation considerable discussion ensued with regard to the proposed electric lighting, Alderman Broughton taking exception to the decision arrived at by the Gas and Lighting Committee, and expressing his disagreement with the Engineer and the Committee in regard to the system approved of. He held that the continuous current should have been adopted, his idea being that although more costly, it was also safer than the alternating current. Councillor W. Cooper and Alderman Miles defended the Committee's decision, and in the result the Minutes of the Gas and Lighting Committee were confirmed.

CLERKENWELL.—The Works Committee of the Vestry have received a letter from Mr. H. F. Lewis, General Manager of the London Electric Supply Corporation, containing suggestions for the lighting of the parish by electricity. The current might, he says, be supplied either from the Company's Blackfriars sub-station or from a station in Clerkenwell itself. Arrangements could be made whereby the Vestry, after the installation was complete, might work it themselves. The Company were willing to surrender their rights under their Provisional Order for £1,200. The Committee did not, however, think it desirable for the Vestry to take any steps at present in the matter.

COLCHESTER.—Local authorities have evidently followed with interest the proceedings before the Joint Committee which has been considering the Electric Powers Protection Clauses. At the meeting of the Colchester Corporation last week the Roads and Drainage Committee reported that the Telegraph Department of the Post Office had applied for permission to erect poles in several of the streets for the purpose of carrying two telephone trunk wires, and recommended the Council to accede to the application. After some discussion the matter was referred back to the Committee in order that they might take the necessary steps to insure that these telephone wires should not be in positions where they might in the future interfere with electric lighting wires or wires in connection with electric tramways.

CORK.—At their last meeting the Corporation resolved to adopt overhead wires for the proposed electric tramway.

CROYDON. The Croydon Corporation on Monday resolved, subject to the sanction of the Local Government Board, to adopt the electric light for the centre of the borough at an estimated cost of £25,000.

DUNDEE. Messrs. Urquhart and Small, electrical engineers, reported to the Gas Commission at their monthly meeting on Thursday last that the work in connection with the lighting installation was now practically completed, and the whole of the work under the various contracts had been properly carried out. The installation had cost £19,607. 12s. 7d., including £599 for extras.

KENDAL.—Contracts for the whole of the work in connection with the proposed new Town Hall have been entered into, with the exception of the lighting. The Town Hall Committee are considering the advisability of lighting the building by electricity, but have not come to a decision.

KIEFF.—The British Consul for the district of Odessa, in his report, describes the electric tramway and the electric lighting arrangements of the town. The Company, which possesses the contract for street lighting, supplies the theatres, many of the principal shops, and private houses; but as the rates charged are rather high a large number of private consumers have their own plant, &c.

LEICESTER.—At a meeting on Monday of the members of the Leicester Co-operative Society it was decided by a large majority to light the premises by electricity, and the Committee were empowered to proceed at once with the work.

MAIDENHEAD.—Messrs. Pritchetts and Gold have notified the Town Council of their intention to apply for a Provisional Order authorising them, or a Company to be formed by them, to supply electricity in Maidenhead. At their last meeting the Council referred the matter to a committee for consideration.

NORTHAMPTON.—At the last meeting the Town Council decided to fit up the Old Reading Room for the electric light at an estimated cost of £30.

OXFORD.—The Oxford Electric Company took the opportunity of the Royal Wedding celebration to introduce a number of artistic and effective electrical devices in the general illuminations of the town, amongst which was included a trophy of flags with arc lamps suspended, accompanied on each side by photographic transparencies of the Duke and Duchess of York.

PERTH.—The newly-registered Caledonian Electric Supply Company (Limited) have informed the Town Council that they propose to apply to the Board of Trade for a Provisional Order authorising them to supply electricity within the Burgh of Perth, and asking the consent of the Corporation. Their letter has been referred to the Lord Provost's Committee for consideration.

POPLAR.—At Tuesday's meeting of the Board of Works the Works Committee recommended that now that Parliament had confirmed the Poplar Electric Lighting Order the clerk report at the next meeting on the subject, and the position of the Board on the matter. It was decided that the clerk should bring up an exhaustive report on the subject, with special reference to the experience of St. Pancras.

ROTHESAY.—The Rothesay Harbour Trust and Town Council at their last meeting notified the Caledonian Electricity Supply Company (Limited) that a proposed application by the Company for a Provisional Order for supplying the electric light to Rothesay would not be supported by the Council.

ST. ALBANS.—The City Council, at their last meeting, resolved that it was expedient that the city be lighted by electricity, and a Committee was appointed to consider and report on the steps to be taken for carrying out the work.

SEVENOAKS.—The Local Board have referred to the Lighting Committee a letter received from Mr. W. Hemmant, asking the support of the Board for an application to be made by him to Parliament for an Electric Lighting Order for the district.

TIVERTON.—At the meeting of the Town Council on Wednesday last the Town Clerk and the Borough Surveyor reported the result of an interview they had had with Sir Thomas Blomefield at the Board of Trade, when a promise was given that any application for an extension of time of the lighting Provisional Order obtained by the borough would not be opposed by the Board. The Town Clerk was authorised to make formal application for the extension.

TUAM.—The Board of Guardians have received a notification from the Tuam Electric Lighting Company (Limited) that they propose to apply to the Board of Trade for a Provisional Order enabling them to supply electricity within the Board's district.

TUNBRIDGE WELLS.—At the meeting of the Corporation on Wednesday last week the report of the Electric Lighting Committee was under consideration. The Committee recommended the Council to approve the plans prepared by Mr. Preece for the purpose of establishing a central station for the supply of the electric current for both public and private lighting, and to apply to the Local Government Board for sanction to borrow the sum of £13,000 for this purpose. After a lengthy discussion the recommendation of the Committee was adopted.

WORTHING.—At the last meeting of the Town Council the report of the Highways Committee, recommending the Town Council not to take immediate action in the matter of lighting the town by electricity, was approved.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published as compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-second half-yearly ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, E.C., under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. George Draper) having read the notice calling the meeting and the minutes of the last meeting, which were confirmed, the report of the Directors was taken as read.

The CHAIRMAN then stated that the gross revenue for the half-year ended March 31st last had been £372,852, or a decrease of £9,355 compared with the gross revenue for the corresponding period in the previous year. Analysing the receipts from various sources, they found an increase of about £3,000 in the message receipts. There was a reduction in the traffic with several places, especially South America and Portugal, but this was more than recouped by the increase in other directions, notably South Africa, Egypt, Turkey, India, and beyond. The reduction in the gross revenue was due to their having received £17,700 from their investment in the shares of the Eastern and South African Telegraph Company as against £29,500 in the corresponding period of the previous year, or a decrease of £11,800. The Eastern and South African Company was practically an arm of their own Company, but for many reasons the two Companies were worked separately. The large bulk of the shares was held by their own Company. The total ordinary expenses for the half-year ended March last had been £102,499, compared with £105,820 in the corresponding period of 1892, showing a decrease of £3,321. The general expenses in London had been £9,369, or a decrease of £220, and the working expenses at stations had amounted to £79,926, being an increase of £1,231. Several of the items under this head showed substantial decreases, and the principal increase was in the salaries and wages of their staff at the stations, where there had been an increase of 30 clerks. They had also to take into account the operation of the scheme adopted some years ago to provide a regular scale of promotions for the younger men as they qualified themselves. Special repairs to buildings at stations had cost £1,974 less, and in connection with negotiations with foreign Governments there had been a decreased outlay of £1,375. Other telegraph companies hiring their ships had been charged a proportion of the depreciation for the period the ships were on the work of those companies. They had, therefore, for the half-year under review a charge of only £2,245 against revenue account for maintenance ships' fund, against £4,000 in the corresponding period of 1892. The expenses attending repairs and renewals of cables had been £32,533, being less by £20,882. They had received during the half-year over £26,000 for the hire of their ships for cable repairing purposes, and he thought they would regard this as very satisfactory. There was no position which the ships occupied so satisfactory to the Company as when they were doing nothing, but they had recently seen that while they were doing nothing for the Company they could find employment for them in working for other companies. They kept their fleet fully manned and in a thorough state of efficiency ready for repairs at short notice. After providing the usual amount for interest on Debentures Debenture stock, and Preference shares, they were able to propose the usual final dividend of 1½ per cent., and a bonus of 1½ per cent., making with the interim dividends already paid, a total distribution of 6¼ per cent. for the year ended March, 1893, and to carry the sum of £88,000 to the reserve fund against £66,000 a year previously. Last half-year, when he addressed them, he expressed his belief that he was submitting to them the best statement of accounts they had ever presented to the shareholders, but

Digitized by Google

he thought they had materially improved their position in the past half-year. He only regretted that this improvement was more or less attributable to a great many of the disasters of which they had heard. Their cables were used for commercial purposes in good times, and when bad times came they were also employed in order that such times might be brought to an end as quickly as possible. When in previous years wars had occurred they had always endeavoured to help those who could not help themselves and had done what they could to ameliorate the conditions of the wounded soldiers and sailors. When the disaster to the "Victoria" occurred the other day, they found that there were many persons in this country who were extremely anxious to know who had been saved. He therefore at once communicated with Admiral Hoskins, informing him that whatever he or the Admiral at Malta thought ought to pass over the Company's lines free would be gladly accepted by them. As they were aware, the Company had been publicly thanked in the House of Lords by Earl Spencer. He was quite sure that the shareholders would thoroughly endorse the Directors' action in this matter. They had applied a further sum of £54,077 from reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other capital expenditure, so that their capital expenditure, with the exception of some small additions to their land and buildings, remained at the same figure as last year. The total amount applied out of the reserve fund from time to time now reached the substantial sum of £1,256,822. They had thus practically duplicated and, in some cases, triplicated their system without increasing their capital. By keeping down their capital they secured in every way something like a permanent income. They could not stand still in such a company as theirs. An arrangement had been entered into with the Government for laying a cable to connect the Islands of Seychelles and Mauritius with Zanzibar and the Company's general system of cables and he believed that before the end of the year they would complete this important additional link to their very important chain of submarine cables. He might state that several other persons had applied for the Mauritius concession, but none of them were in the position occupied by this Company. They had had another battle. After practically obtaining a concession from the Portuguese Government to lay a cable connecting the islands of the Azores with Lisbon, some French people came in, and, backed by influence of their Government, they obtained the concession. The Portuguese Government, however, required a guarantee of £20,000, which was paid, but the French Government then backed out of supporting their people, who could not carry out the work. Their £20,000 was therefore forfeited, and the Eastern Company again stepped in and and succeeded finally in gaining the concession. He then expressed great regret at the loss which the Company had sustained by the death of Sir James Anderson—the late Managing Director—who had rendered the Company invaluable services for many years. His (the Chairman's) son—Mr. J. Denison Pender—had been appointed to the position, having been trained for the work for a long time. He was acquainted with very few men who knew more about the work than his son did, but he might state that the suggestion that Mr. Denison Pender should be appointed had not come from him so much as from other members of the Board. He concluded by moving the adoption of the report and the payment of the dividends and bonus recommended.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion. Some discussion followed, and in answer to questions,

The CHAIRMAN said that he received nothing for the time he expended on the business of the Company when he visited their stations beyond his regular remuneration as a Director, although he was the means of doing a good deal of work for the benefit of the Company on such occasions. The contract for the Azores cable was brought about, he believed, from the result of his visit to Portugal. Whenever he went beyond the sea-board he made no charge to the Company, and he paid for the expenses of any friends who accompanied him. He thought, under all the circumstances, that it would have been a graceful thing if the Company had offered to pay the expenses he incurred out of pocket on the occasion of these trips, which, in the interests of the Company, he wished he could take oftener. His time, however, was too valuable to allow him to do so. If they had not carried out their policy strictly of forming a large reserve fund, and of practically duplicating, and in many cases triplicating their system, without materially increasing their capital, they would not be in their present strong position. This policy had greatly increased the market value of their shares and stocks, but they could not have their cake and eat it too. If they were not paying an extra 1 per cent. in dividend they considerably strengthened the value of the share property. Whenever, however, they felt that they could prudently pay a higher dividend they would only be too happy to do so. The resolution was then unanimously adopted.

On the motion of Mr. BAYNES, seconded by Mr. JOHN NEWTON—both of whom expressed deep regret on behalf of the shareholders at the loss sustained by the Company in the death of Sir James Anderson—a vote of thanks was passed to the Chairman, Directors, and staff.

The CHAIRMAN acknowledged the vote, and the meeting then separated.

[*We shall publish a full report of this meeting in our next issue.*]

West African Telegraph Company.

The eighth ordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, Sir John Pender, G.C.M.G., M.P., presiding.

The SECRETARY (Mr. John Cambrook) read the notice calling the meeting, and the minutes of the previous meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: Before asking you to approve the report I will, as usual, make a few remarks. Our gross revenue for the year 1892 amounted to £60,923 as against the takings for 1891 of £60,214, showing an increase of £709. The receipts from Portuguese stations show a large falling off, which, however, is balanced by a corresponding increase in guarantee received from Portugal. The receipts from French stations owing to military operations in Dahomey, show an increase. The Cape purse receipts also show an improvement, but owing to the falling off traffic with South America and British stations, and also to the fact we are making a comparison with a period when we carried a large amount of British traffic during the interruption of the African Direct Cable Lagos-Accra cable, the net increase in revenue, is as already mentioned £509. As stated in the report, we have again made a very heavy loss exchange, which affects our revenue by over £8,000. We are doing that is possible to minimise the loss in future transactions. The Portuguese Government have already sanctioned our collecting at a higher rate on certain classes of traffic, but they have not yet admitted the principle of allowing us to collect at the higher rate on the whole traffic. The bulk of the loss, however, is made in the remittances of the amount paid to us in Portugal by the Government on account of the guarantee. The total working expenses for 1892 amounted to £20,019 against £20,883, or a decrease of £864, the principal decrease being under the heading of general expenses in London £133; working expenses at Accra £427; foreign agency, £222; depreciation of cable stock, £82. Interest to cables amounted to £13,964, against £2,213 in 1891, or an increase of £11,751. As will be seen from the details given in Abstract C attached we have unfortunately had to effect an exceptional number of repairs. The work has been carried out by the Eastern and the Eastern and South African Companies' ships at actual cost, but notwithstanding this arrangement, the expense has been very considerable—so much so that the Directors consider it advisable to carry forward the whole balance of £2.410 without distributing anything in the way of dividend. As announced in the report, we have been obliged since the date of the accounts to incur further heavy expenses in connection with the diversion of the cable off the mouth of the Congo, but I trust when the work is carried out we shall be relieved from expenses of such an exceptional nature for some years to come. As a large proportion of our receipts derived from the joint-purse arrangement for the Cape traffic it is essential that we maintain our link in the alternate route to the Cape in a thorough state of efficiency. The expenses in connection with the diversion of our cable beyond the influence of the currents caused by the river Congo will involve a considerable burden on this Company for some time to come, but we are convinced that this course will be the most economical one, and in the end be in the best interests of the Company. The most rigid economy is practised in the management of the Company, and we look forward hopefully to better results in the future. These are the real facts of the case. A very important event has taken place since I last had the pleasure of addressing you, namely, the death of Sir James Anderson, who was from the inception of the Company, the Managing Director. We have lost in him a gentleman who took a very warm and lively interest in the Company, as he did in all the Companies with which he was connected. The fact of this Company practically completing our cable system round Africa was also, I think, looked forward to by us with a very great deal of satisfaction; it is with much regret, therefore, that I am obliged to say we are not in a position to pay a dividend. I look upon this circumstance, however, as temporary, and I think that when I address you at our next meeting we shall be able to present a better state of things. There are two circumstances which have been greatly against us, one of which is the heavy amount we lose by exchange. It is a very serious amount for a small Company like ours, and we are trying to persuade the Portuguese Government to enable us, not only by their own action in regard to the Government messages, but also with respect to the general messages, to recoup ourselves for the heavy loss we are now sustaining. The Government have refused to make any change in regard to their own messages, but I regard that as an unfair view to take, and not in accordance with a strict reading of the agreement with the Government. We shall not, however, fail to bring pressing on them to do us full and fair justice. The next important difficulty we have had to contend with, and which we have gone into most carefully, is in regard to the diversion of the cable mentioned in the Report off the river Congo. We have decided to divert that cable, which at the present moment crosses the mouth of the Congo. From our experience of this river and other rivers similarly situated we find that there are under-currents which we cannot understand, and their influence injurious. We have, therefore, decided to carry this cable about 140 miles out to sea, so as to be entirely free of the action of these under-currents. The removal will cost a good deal of money, but we hope it will enable us to give a certain service, and to secure the Company from interruptions and breaks. With these remarks I beg to move

"*That the report and accounts for the year ended December 31, 1892, submitted to this meeting be and they are hereby received and adopted.*"

Sir HENRY C. MANCE seconded the motion.

The CHAIRMAN, in answer to Dr. Kelly, stated that the interest on the Debentures, and the other claims of the debenture holders, had been met, both under the deed and as a matter of business, before the shareholders could receive any return. If the cables had not broken so many times this year, and thus cost them £13,000, the shareholders would have been given a dividend. He held £5,000 in the Debentures besides his shares; and his son had 1,000 shares. They would have been only too glad to have paid a dividend if they could have done so.

The resolution was then carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. J. DENISON PENDER, Sir Henry C. Mance was re-elected to his seat at the Board.

Mr. ALEXANDER HENDERSON afterwards moved, and Mr. CLIFFE OWEN seconded, the re-election of the auditors, Messrs. Price, Dever, Griffiths & Co.

The motion was carried unanimously, and the proceedings terminated.

National Telephone Company (Limited).

The following is the report of the Directors for the year ended April 30, 1893, to be presented to the shareholders at the Thirteenth Ordinary General Meeting to be held at the Cannon-street Hotel on Tuesday next, the 18th inst., at 1 p.m. :—

The income accrued in respect of the business of the year amounts to £583,590. 2s. 11d., as compared with £463,741. 5s. 4d. for the preceding year, being an increase of £119,848. 17s. 7d. The rentals carried forward this year for unexpired terms of running contracts amount to £285,020. 7s. 8d., as compared with £234,370. 11s. 2d. for the preceding year, or an increase of £50,649. 16s. 6d. The working expenses and other charges (excluding debenture and other interest) amount to £311.644. 10s. 2d., as compared with £236.252. 0s. 5d. for the preceding year, being an increase of £75,392. 9s. 9d. The net result for the year, after deducting the Post Office royalties amounting to £54,220. 9s. 10d., is a profit balance of £217,725. 2s. 11d., as compared with a balance of £187.249. 19s. 3d. for the preceding year, being an increase of £30.475. 3s. 8d. Out of the available balance an interim dividend at the rate of 6 per cent. per annum on the First and Second Preference shares, and 5 per cent. per annum on the Third Preference and Ordinary shares has already been paid. The Board will recommend a further payment at the rate of 6 per cent. per annum on the First and Second Preference shares, and 5 per cent. per annum on the Third Preference and Ordinary shares, making the dividend for the year 6 per cent. on the First and Second Preference shares, 5 per cent. on the Third Preference shares, and 5 per cent. on the Ordinary shares The distribution on the Ordinary shares of 1 per cent. less than in the preceding year is recommended by the Board chiefly in view of the desirability of strengthening the position of the Company by carrying an adequate annual sum to the reserve fund. The Board propose under No. 113 of the Articles of Association to transfer to the reserve fund £30,000 (bringing that fund up to £134,627. 3s. 6d.), and to carry forward the balance of £2,194. 14s. 3d.

A reference to the capital account shows that during the year the purchase has been completed of the undertakings of the Western Counties and South Wales Company, the Sheffield Company, and several other minor companies. Though involving the outlay of £345,776, the Board believe that these purchases will be advantageous alike to the public and the shareholders, as enabling the telephone business of the country to be developed and conducted more efficiently and economically than it could possibly be if carried on in a disjointed fashion by a number of small and separate administrations. Since the end of the past financial year arrangements have been made for acquiring the Telephone Company of Ireland.

The Board have had to consider their position in relation to the New Telephone Company, which was launched in avowed competition with the National Company. The promoters of that enterprise soon began to appreciate the serious difficulties which lay before them, and, as the result of discussion, accepted the conclusion that if the shareholders were to be secured a reasonable return upon their capital it would be better, in the public interest, to work in harmony with the National Company, adopting as far as practicable the better features of the two systems. This resulted in an agreement, under which the National Company subscribed one-third of the capital of the New Company, and were represented on the Board of that Company. Subsequently it became apparent that the policy of the Government in assuming possession of the Trunk wires, forming the inter-town communication of the country, would greatly complicate the position of the licensed companies, and make unity of administration and interest essential to efficiency and success; therefore, upon the sudden death of the late Duke of Marlborough, who was the enthusiastic and moving spirit of the New Company, those who were associated with him recognised the necessity of still closer union with the National Company, and matters have ended in the National Company acquiring, partly by purchase and partly by the exchange of New Company's shares for National shares, nearly the entire interest in the New Company.

During the year negotiations of a difficult and complicated character in relation to the acquisition by the Government of the Company's trunk lines have been carried on with the authorities of the Post Office. The Board are gratified to be able to report that a draft agreement is now in course of preparation, which it is hoped may be shortly accepted and ratified by the contracting parties.

The rapid growth of the Company's business, and the expansion of its territory consequent upon the absorption of the several minor companies, coupled with the increasing responsibilities of the Board involved in the closer relations with the Post Office, pointed to the importance of bringing into the counsels of the Company some new members of a certain public position and experience. This necessity was unanimously recognised, and acting in the spirit that no question of personal interest should stand in the way of the interest of the shareholders, two vacancies were created by the voluntary retirement of Mr. John Bruce and Mr. Peter Garnett. The Board, under the powers conferred on them by the articles, were enabled to fill up these vacancies by the election of Lord Balfour of Burleigh, and of Sir Albert K. Rollit, M.P. The same spirit which actuated his two colleagues was displayed by Colonel R. Raynsford Jackson, who readily vacated his position as Vice-President of the Company in order that it might be filled by Lord Balfour of Burleigh, whom it was considered desirable to place in that important office.

At the general meeting four Directors retire, and being eligible offer themselves for re-election, viz., Lord Balfour of Burleigh, Mr. Charles Swain Agnew, Mr. George Hunter Robertson, and Sir Albert Kaye Rollit, M.P. Lord Balfour of Burleigh and Sir Albert Kaye Rollit, M.P., elected to retire, considering it would be respectful to the shareholders to submit their recent selection by the Board to the judgment of the proprietors. The auditors, Messrs. Welton, Jones, and Co., also retire, and are eligible for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

CALEDONIAN ELECTRIC SUPPLY COMPANY (LIMITED).—This Company has been registered in Edinburgh, with a capital of £100, divided into 100 shares of £1 each, to carry on the business of electrical engineers, electricians, suppliers of electricity, manufacturers of electrical apparatus, mechanical and chemical engineers, and to establish other businesses of a like nature. The following are the first subscribers (with one share each) :—Alex. F. Carmichael, electrical engineer, 7, St. Bernard's-row, Edinburgh; J. I. Hall, electrical engineer, 5, Shandon-crescent, Merchiston, Edinburgh; Henry R. Taylor, architect, 50, George-street, Edinburgh; W. K. Rose, advocate, 1, Drummond-place, Edinburgh; Alex. Ross Mackay, engineer, 10, Graham-street, Edinburgh; Peter Mackenzie, S.S.C., 3, Hope-street, Edinburgh; Alex. Slater, electrical engineer, Public Library, Edinburgh.

MISCELLANEOUS.—Northern Steel and Hardware Company (Ltd.). Capital £10,000, in £10 shares.——Walter Danks and Co. (Limited), iron merchants, &c. Capital £12,000, in £20 shares.

AUTOMATIC ELECTRICAL CORPORATION (LIMITED).—In reply to a notice from the Registration Department respecting the non-filing of the necessary returns, it is stated that the works have been closed and that the Company is in fact defunct. With a capital of £75,000, in £20 shares, the Company was registered in 1888 to act as undertakers for the supply of electricity, and in particular to acquire and turn to account an invention relating to an improved galvanic battery with apparatus for automatically supplying liquids thereto.

BAILY, GRUNDY, AND BARRETT (LIMITED).—The statutory return of this concern, made up to May 26, 1893, has been filed. Out of a nominal capital of £10,000 in £5 shares, 602 have been taken up, the full amount called, £2,950 paid, and £60 unpaid.

BARNET AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The usual return of this Company, made up to January 14, 1893, has been recently filed. The Company has a nominal capital of £5,000, divided into 490 Ordinary shares of £10 each, and 100 Founders' shares of £1 each. 80 of the former and the whole of the latter have been taken up, of which the latter were issued as fully paid. Upon 60 Ordinary shares, the full amount has been called, while upon the remainder £5 per share has been called, resulting in the payment of £700.

BROWETT, LINDLEY, AND COMPANY (LIMITED).—The annual return of this Company filed on June 17, 1893, shows that 200 Preference and 1,362 Ordinary shares, each of £10, have been taken up. 800 of the latter class have been considered as fully paid, while the full amount has been called, and £7,620 paid on the remaining shares.

CALLENDER'S BITUMEN TELEGRAPH AND WATERPROOF COMPANY (LIMITED).—The annual return of this Company, made up to May 23rd and recently filed, shows that 6,316 shares of £10 each out of a total of 8,000 have been taken up. 3,000 of these were issued as fully paid, while the full amount has been called and paid on the remaining 3,316 shares.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—A petition has been presented by Messrs. Beckett and Co., bankers, of Leeds, for the winding up of this Company, and is down for hearing at the Royal Courts of Justice on the 21st inst.

CITY NOTES, &c.

BURTON-UPON-TRENT.—The Town Council of this Borough are inviting tenders for a Three per Cent. Loan, to be partly devoted to their electric lighting scheme. The minimum is £97 per cent., the total amount offered being £135,000. The stock is fully secured by borough rates.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 9th were £1,069, as against £733 for the corresponding period of last year, being an increase of £336. The total receipts for the half-year amount to £1,069, against £733 in the corresponding period of 1892, being an increase of £336.

COMPAGNIE BELGE DU TELEPHONE BELL.—At a recent meeting of shareholders it was decided to wind up this Company.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). The Directors have declared an interim dividend for the half-year ended June 30, 1893, at the rate of 7 per cent. per annum on the Preference shares. The transfer books will be closed from July 14th to July 24th inclusive. The electric current sold by this Company during the quarter ended June 24th last amounted to £5,848, as against £6,643 in the corresponding period of 1892.

MADRAS ELECTRIC TRAMWAY COMPANY (LIMITED).—The *Madras Mail* of June 20th states that the Government of Madras has refused to grant the extension of six months applied for by the Company, in which to construct the tramway, on the ground that the condition necessary to the extension, that £75,000 capital should be subscribed, has not been complied with. The Company, therefore, loses its concession, and the deposit of 10,000 rupees is forfeited to the municipality.

TELEGRAMS TO BRAZIL.—The Eastern Telegraph Company (Limited) notifies that in accordance with instructions received from the Inter-

Digitized by Google

national Bureau at Berne, telegrams for Brazil can only be accepted in plain language without figures or code words of any kind, and, further, that messages containing any allusion to Brazilian political affairs cannot be accepted.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 7, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,372.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 792.—Vol. XXXI. FRIDAY, JULY 21, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

A comparison between the results which we publish this week of the tests that have been recently made by Prof. Kennedy, upon the latest pattern of a Parsons steam turbine, and the results of former tests, will show a most satisfactory improvement in this engine in most, if not all, directions. Our readers will remember that in Vol. XXX., p. 25, we commented on the report of the tests made by Prof. Ewing *last* August. We were then able to give a very favourable comparison between the results of those tests and the previous performances of a Parsons engine. This generator which, in 1888, consumed a very large amount of saturated steam per horse-power hour, was found by Prof. Ewing to have reduced its full-load consumption to 27·6lb. per E.H.P. hour or 37lb. per Board of Trade unit; one of the principal sources of improvement being the use of superheated in place of saturated steam. The normal output of this plant was 100 kilowatts, the speed being as high as 4,800 revolutions per minute. The plant recently tested by Prof. Kennedy was "in external dimensions almost exactly the same as that tested by Prof. Ewing"; the speed, 4,500 revolutions per minute, was somewhat lower, and the pressure and amount of superheating at full-load were substantially the same. Yet the maximum output which it was possible continuously to maintain from the plant was greater in the ratio of about 150 : 100, and the consumption per unit of energy was considerably reduced. The steam consumed per E.H.P. hour was found to be only 20·3lb. at full load, as against 27·6lb.; or, per Board of Trade unit, 27·2lb., as compared with 37lb. in the former trial, showing an improvement of nearly 24 per cent. Thus in the several points of output, speed, and efficiency, the engine seems to have been overhauled, altered, and substantially improved. There is also a commensurate improvement of the efficiencies at reduced loads.

Prof. Perry supplies us this week with a short article which illustrates numerically and graphically the effects which take place when an alternating-current circuit is made up of a choking coil and condenser placed in series. His curves are similar to those of Messrs. Bedell and Crehore, given in *The Electrician*, Vol. XXX., p. 6, and which have since been incorporated in their work on alternating currents. The present article, however, unlike that of the American authors, clearly explains the method of calculating the curves, and contains numerical data, which enables any one interested to form a more correct idea of the nature of the changes which occur. The three curves given by Messrs. Bedell and Crehore appear practically identical, so sharp is the peak to which they rise. In reality, however, these curves differ considerably from one another. The excessive rise of current which all these curves show when the inductance of the circuit attains its critical value, is due to a condition of things which can hardly be easily realised with actual coils and condensers.

The investigations of Dr. Lewis Jones on the duration of the discharge of an induction coil, which we print this week, present several points of interest. He has used a very sensitive chemical recording device, far more delicate than that of Bain; and a tracing made by the current from the mains of the Metropolitan Electric Supply Company shows that there is no dragging out of the record, either by continuation of the chemical action or by accumulation of colouring matter under the style. No spark-gap was used, and the resistance of about 1,000 ohms, offered by the damp paper on which the record was made, approximates to that of the human body. The conditions of the experiment, therefore, much more nearly resemble those of the ordinary medical application of an induction coil than those of the researches of Blaserna and of Colley, to which Dr. Jones refers. Whether a further examination would reveal oscillations in the tailing-off of the "break" discharges or not is of small importance from a medical point of view. The result shows that the discharge approximates much more to an ordinary alternating current than to an abruptly intermittent current, and encourages the hope that medical men will be able before long to measure these minute currents, and to express their doses in some intelligible measure.

In an article on the electromagnet, published in this issue, Dr. Frölich appears surprised that no attempt has yet been made to unite the theories of Dr. Hopkinson and Mr. Kapp. For our part, however, we have so long regarded these two theories of the magnetic circuit as essentially the same that no attempt to reconcile them seems necessary. Dr. Hopkinson's mode of expressing the law was more orthodox than that used used by Mr. Kapp, but the latter was much more easily grasped. Mr. Kapp introduced the simple and most useful notion of magnetic resistance, and although the other theory also involved this idea, it was not so clearly

Digitized by Google

expressed. On the other hand, Mr. KAPP somewhat marred the value of the Paper in which he first stated his theory by introducing an empirical formula for the law connecting magnetising current and induced magnetism, which unfortunately did not at all well coincide with experimental results. Dr. FRÖLICH has been prominently connected with the various attempts which have been made to get an empirical formula for the law of saturation; but although a great deal of skill has been spent on these efforts, we do not think the results obtained are a sufficient compensation for the labour. Dr. HOPKINSON made no attempt in this direction, simply referring to the experimental curve connecting magnetising force with magnetism, and this method is the one universally adopted in design.

WITH reference to M. D'ARSONVAL'S ingenious use of a mercury thermometer to measure alternating magnetic fields, which was described on p. 378 of our last issue, it has been pointed out to us that much the same idea was mentioned by Mr. MORDEY in the course of the discussion on Mr. SWINBURNE'S Paper on "Transformer Distribution," read before the Institution of Electrical Engineers in February, 1891. Mr. MORDEY pointed out that a very good magnetic leakage detector for transformers consisted of a spirit thermometer and a mercury thermometer side by side; the leakage lines setting up eddy currents in the mercury and not in the spirit, and heating it and not the other thermometer. We may add that for weak alternating fields, in which the eddies set up in the mercury are not sufficiently powerful to render negligible the ordinary variations of temperature, M. D'ARSONVAL uses a petroleum or an air thermometer, in the bulb of which he places a little copper tube.

WE cannot, as a rule, find space in our columns for recording fatal accidents with electric light on the other side of the Atlantic, one reason being that the conditions of work differ so greatly from those in this country, that no useful lesson can be learned from them. The reprehensible practice of switching current on to mains while there is a possibility of workmen being in contact with the wires is, we hear, once more responsible for the death of a lineman. The accident occurred at Ottawa, the lineman not having finished the junction of the line with a building when the current was switched on. The remedy for this risk is the strict observance of the pre-arranged time at which the mains are to be re-connected to the supply. Rubber gloves are only fit for use by thoroughly experienced engineers who know the untrustworthy nature of the protection which they offer.

IT is a curious irony of fate that the London Electric Supply Corporation, which, as we remarked a week or so ago, reckoned upon complete immunity from actions for nuisance in connection with its electric lighting operations, should have been perhaps the worse bitten of any; at any rate, publicly, for there is, of course, such a thing as settling a claim privately out of Court. The case of "Blackie *v.* Electricity Supply Corporation," following immediately upon that of Dart *versus* the same Company, must afford no little relief to those responsible for the running of generating machinery planted in the heart of densely-crowded districts. Juries are notoriously "down on" railway companies, and the existence of high-pressure boilers and high-speed machinery in the closest proximity to shops, hotels, and dwelling-houses, might very possibly have set the "heavy damages" chord of the juryman's heart into vigorous vibration, and have rendered him oblivious to all considerations of justice and equity. The result of two actions referred to, however, show that this is not the case, and it is something to be thankful for.

A RECENT issue of the *Electrical Engineer* of New York contains a Paper and a short note on "Calculating Armatures." The title puzzled us at first, as our thoughts were carried to phenomenal "calculating boys"; but we find that this is not an announcement of a new prodigy, but merely a new method for getting out armature quantities. The method "is based on the analogy between the torque at the periphery of the armature and the pressure on the piston of a steam engine." If occult analogies can ever evolve good armature proportions, this one may do as well as another. In a similar manner we might design a flap-valve from its analogy with a five-barred gate, or an arc lamp from its analogy with the rush-light.

The Heilmann Locomotive.—The trials of this electric locomotive have been commenced at Havre.

The Waterloo and City Railway.—The Unopposed Bill Committee in the House of Lords passed the Waterloo and City Railway Bill last week.

Cable Interruptions and Repairs.—

	Interrupted.	Repaired.
St. Thome—Loanda	May 30th.	July 18th.
Paramaribo—Cayenne	April 15th.	—

Eastbourne.—On Sunday last many of the streets of Eastbourne were flooded to the depth of several feet. The circuits of the local electric lighting Company were not, however, interfered with in any way.

University College, Bristol.—The 1893-94 Session of this college begins on October 5th. Information as to the Electrical Engineering and Chemistry courses will be found in our advertisement columns.

Aluminium Reduction.—The Pittsburg Reduction Company has, it is said, contracted with the Niagara Falls Power Company for 6,500 E.H.P., for use in a new aluminium plant to be erected at Niagara Falls.

Appointment Vacant.—The Committee of the Manchester Municipal Technical School invite applications for the post of Assistant Lecturer in the Physical Department. For further particulars see our advertisement columns.

Patents in Canada.—Of 3,417 patents granted last year in Canada, 2,227 were taken out by American citizens, 671 by Canadians, 298 by Englishmen, 106 by Germans, 26 by Frenchmen, and 89 by persons of other nationalities. The receipts amounted to about £17,000, and the profits £9,000.

The American Institute of Electrical Engineers at the Chicago Exhibition.—The Exhibition headquarters of the American Institute of Electrical Engineers are, says the *Electrical Engineer* of New York, being rapidly put into habitable condition. The rooms are at the south end of the Electricity Building, and will be fitted up handsomely and comfortably for the reception of members.

Platinum.—The available information as to the Russian platinum industry has been increased by a visit made by Mr. George F. Kunz to the district, and described by him in the recently published eleventh census report of the mineral industries of the United States. The average daily yield of the

Digitized by Google

whole of the Government district is about 9lb., worth about £2 per ounce, and the yearly production is about 1,620lb.

An Electrical Horse-whip.—A recent number of *Electricité* describes a horse-whip which is constructed so as to give a slight electric shock to the animal upon which it is administered. The handle, which is made of celluloid, contains a small induction coil and battery, the circuit being closed by means of a spring push. The extremity of the whip consists of two small copper plates, insulated from one another, each of which is provided with a tiny point. The plates are connected to the induction coil by means of a couple of fine inuslated wires. Electric shocks of considerable severity have, we believe, been used for some time by horse trainers; but the apparatus described in *Electricité* appears to be unlikely to injure or inflict unnecessary pain on the horse.

Long-Distance Telephony and Railway Passenger Traffic.—An American electrical contemporary suggests that the cause of all the recent experimenting and the willingness of the American Railway Companies to put on faster trains between Chicago and New York is not entirely due to competition among themselves, nor any special demand by the public, but to the great strides made in the telephone business, the use of the telephone for the last three or four years having somewhat cut off business traffic on the railways. It is possible, our contemporary points out, for a Board of Directors, part of whom live in Philadelphia and a part in New York, to hold its meeting by telephone, and the law courts have decided that such meetings are legal.

Electric Lighting in Europe.—Mr. Wm. McDevitt, electrical expert of the Philadelphia Fire Underwriters' Association and the Philadelphia Fire Patrol, recently paid a visit to Europe to examine, from the underwriters' standpoint, into the methods of wiring employed here, and he has just made a report. The general impression left on Mr. McDevitt's mind after looking at our underground work is "that an enormous amount of money has been spent in the hope that some day it may pay. From the complaints of the electric companies it is very evident that, so far, they are very much handicapped by this immense outlay." With regard to electric fire experiences in Europe and America, Mr. McDevitt arrived at the—to him—satisfactory conclusion that the nations of the two continents were "all pretty much on a level."

Copper v. Silver.—With a view to maintaining in some measure the price of silver, economists are now on the look out for a new commercial use for this much depeciated monetary metal. We are afraid that silver, cheap as it is, is not yet cheap enough for extensive use in the electrical industry. Silver is at present half-a-crown an ounce, and is expected to reach two shillings; copper is about £45 a ton, or ½d. per ounce troy. To compete with copper as a conductor, therefore, silver at two shillings an ounce would have to exhibit some marked improvement upon the electrical properties of copper, which, unfortunately, it does not do; in fact, from the electrical point of view silver and copper are practically the same metal, their conductivity, temperature coefficient, and tensile strength being very much the same.

The City and South London Railway.—In the House of Commons on Monday Mr. Byles asked the Chancellor of the Exchequer if he was aware that the City and South London Railway Company charged fares exceeding a penny per mile for the distance actually travelled by the passenger; that on these fares exceeding a penny per mile no passenger duty had been paid; on what grounds this privilege had been permitted to the City and South London Railway; and on what terms other railways might obtain a participation in this privilege. Sir J. Hibbert said that the facts were not as stated in the question. The Company was liable for duty on the fares received at the rate of over a penny per mile. But owing to the peculiar method adopted for the payment of fares it was difficult to determine the extent to which the Company was liable. An arrangement had been arrived at between the Commissioners of Inland Revenue and the Company, under which the Commissioners were satisfied that the liability was fully discharged.

Mr. Edison's "Albert Medal."—A curious exhibit of Mr. Edison at the Chicago Exhibiton are some samples of the many medals, awards, diplomas, and other decorations which he has been accumulating during the past ten years. Amongst these is the Albert Medal, recently awarded him by the Society of Arts in recognition of his electrical inventions. With this medal is shown the correspondence connected with it. First of all there is a letter from the Prince of Wales, then there is a letter from the English Ambassador, who refers to the "inestimable benefits" which Mr. Edison has conferred "on all nations"; the correspondence prosaically concluding with a letter from a United States Secretary of State to whom the medal was entrusted, informing Mr. Edison that he can have the medal on paying the postage.

The Glasgow Telephone Exchange.—Advantage was taken of the recent Fair Holidays to get the new telephone arrangements in Glasgow made available for the subscribers. For the double metallic connection between the exchange and the subscribers a length of at least 1,000 miles of wire additional had to be run. It is all of silicium bronze, and of 16 B.W.G. In the new switch room and testing-room at the Royal Exchange at least 500,000 soldered joints or connections had to be made, and some 50,000 spring jacks had to be fixed in position, about 5,000 of them in the testing-room. There are about 3,200 subscribers in connection with the Glasgow Telephone Exchange, but the ultimate capacity of the switch-room will be something like 10,000 connections.

Testing for Arsenic.—In cases of medical jurisprudence it is, says *Industries and Iron*, unfortunately often necessary to test for arsenic. It was, and we fear still is, usual to use zinc to produce arseniureted hydrogen. There is great difficulty in procuring zinc absolutely pure and free from arsenic, and as the least trace of arsenic in the zinc might result in untrue evidence being given, which might cost the life of a human being, it seems strange that such a test should ever be used now. It is obvious that zinc should not be employed. A small battery with platinum electrodes will produce the arseniureted hydrogen, if there is any arsenic present, without risk of any misleading results due to impurities. This method was proposed some time ago, but we believe the dangerous method with zinc is not yet superseded, owing to the conservative dread of anything new—especially anything electrical.

The Marking of Foreign Meat by Electricity.—On Wednesday last Lord Onslow's committee, appointed by the House of Lords to consider the practicability of marking foreign meat, held their last sitting for the purpose of taking evidence. At previous sittings it had been suggested that the meat should be marked by electricity, but a doubt arose whether the electrical marking would hasten decomposition, and it was accordingly arranged that two legs of mutton should be experimented upon. On Wednesday Mr. Joseph Kincaid, of the firm of Kincaid, Waller, and Manville, produced a machine which his firm had invented for the purpose of electrically marking meat, and also two legs of mutton (one of which had been marked) which had been in the possession of an independent butcher for a sufficient length of time to test the rate of decomposition. Mr. Kincaid said that though practically there was no difference between the two legs, the electrically marked one was perhaps slightly the better of the two.

Bradford.—On Wednesday last a special meeting of the Gas and Electricity Supply Committee of the Town Council was held for the purpose of conferring with Lord Kelvin, who visited Bradford for the purpose, on the best mode of extending the electricity supply works. Lord Kelvin's written report, which had already been placed before the Committee, stated that he had had a full discussion of the whole subject in conference with Mr. Baynes and Mr. Shoolbred and that after careful consideration of the whole subject, he was of opinion that the best arrangement for improving and augmenting the electricity supply was to adopt the three-wire system recommended by Mr. Baynes. "The method proposed by Mr. Shoolbred," says Lord Kelvin, "whether for a three-wire system or a five-wire system, according to which the adjustments of the pressure for the consumers at different parts of the system are entrusted to automatic mechanism at the feeder ends, is not adapted to give in ordinary circumstances the requisite uniformity of pressure to the consumers, and is liable

Digitized by Google

also to serious dangers and objections." When the time comes for still wider extensions Lord Kelvin thinks a second generating station would be better than adopting the five-wire system. The conference on Wednesday was very protracted, and extended over a period of about three hours.

Telegraphy in Persia.—The mode in which telegraph lines in Persia under native control are erected and worked is described by the British Consul at Resht in reference to the line between Enzelli, on the Caspian, and Resht, and Teheran. In dry weather, he says, the line works fairly well, but in damp or rainy weather it cannot be counted upon. The reason is that the insulators are driven into trees that have branches growing round the hooks and touching the wires; but when a large tree is not available a small one is used, and this often breaks, or the shaking of the slender tree by the wind dislodges the insulator or hook on which it is fixed, and the wire trails on the ground. The Consul has often seen the wire right across the high road, which is followed by hundreds of mules both in Ghilan and Astrabad, not only interrupting telegraphic communication, but endangering the lives of the animals and their riders, more especially when the accident happens on the brink of a precipice. It is not surprising, under these conditions, that telegrams in Persia are not received punctually. In one case a high foreign official telegraphed to Teheran from Europe announcing his intended arrival at Resht in a fortnight. The telegram was received at Teheran the same day by the European line and immediately despatched to Resht by the Persian line. The fortnight elapsed and the high official arrived. The telegram was received in the sender's presence 18 days after its despatch.

Electrical Engineering at the Merchant Venturers' School. The governors of this institution have decided to improve the equipment of the electrical engineering department. For this purpose a complete installation will be provided. It includes two small dynamos of different types, built by the students of the school, and a large 4-pole experimental dynamo, specially built by the Brush Company. The latter has its field-magnet coils so wound that it can be used as a series, shunt, or compound-wound machine; it is also provided with a special exploring coil in the armature, so that magnetisation of the armature can be examined, and the machine is so constructed that an alternating current of slow periodicity can be obtained. These three dynamos will be driven by a horizontal gas engine, and will be used not only for experimental purposes, but also for charging a set of storage batteries placed in the electrical laboratory; from these cells currents will be conveyed to the lecture theatre and to the laboratory tables. During the past few weeks the senior students in the electrical engineering section of the school have been busily engaged in placing the necessary cables and wires throughout the building, and the whole will be in readiness for use during the ensuing winter session. Considerable additions are also being made to the electrical measuring instruments of the school, and it is proposed to utilise the town electrical supply for experiments with alternating currents, as well as for lighting a part of the building. The remainder of the school premises will probably be gradually wired by the students.

Thunderstorms.—On the 5th inst. the ss. "Ludgate Hill" was struck by lightning in mid-Atlantic during a severe storm. The lightning struck the foretopmast and split it in two. The second officer was knocked off the bridge, and a fireman was hurled a distance of 20ft. along the deck.—Further particulars are now to hand relative to the fatalities caused by the storms of last week. At Long Stratton three men and some horses sheltering under a tree were struck by lightning, and one man was killed. Tree-like impressions were discovered on the unfortunate man's body, but his clothes were quite uninjured. In the Midlands two fatalities occurred. In Ireland a man unknown was found dead on the public road some seven miles outside Kilkenny. There was a punctured wound on the left side of the head. The body was much burned, and some trees adjacent to where the remains were found were burned by lightning. In the Knocks district, near Bandon, two men, fearing the iron tools in a forge "would attract the electric fluid," went into the dwelling-house attached. They had scarcely entered the house when a discharge struck the thatched roof which was instantly ignited, and killed them. The forge escaped uninjured. At Burton-on-Trent the lightning struck a house, and not only fetched out the palisading from the front of the house and laid it in the middle of the road, but also knocked down the chimney. The lightning seems then to have passed over two adjoining houses and struck the third house, where it fetched the spout down.

The Sayers Feeder Compensators at Derby.—The following particulars of one of the new compensators for fall of pressure in feeders, constructed by Messrs. Mavor and Coulson, on the lines suggested by Mr. W. B. Sayers in his recent Paper read before the Institution of Electrical Engineers, may be of interest:—The feeder is to be used in connection with the three-wire electric lighting system of the Midland Railway Station at Derby, for which Mr. J. Sayers is responsible. The compensator will be placed in the engine-room, the current to the feeder which it controls passing through it, by which means the pressure is automatically raised by an amount just sufficient to compensate for the drop in the feeder, whatever the current flowing may be. In this way the necessity for hand regulation and pilot wires is dispensed with. The compensator proper consists of a pair of low-pressure series dynamos mounted on the same shaft, and driven direct by a constant-speed motor. The current to the extreme positive feeder traverses one of the armatures, and that to the extreme negative feeder traverses the other. In order to compensate for the drop of pressure in the third wire when a current is flowing in it, the balancing current is taken round the keepers in such a manner as to compensate for the disturbance which is caused by the drop when such a current flows owing to the unequal loading of the two sides of the system. Two sets of compensators have been constructed for the Derby Railway Station, one to carry a maximum current of 500 amperes, and to raise the pressure 1 volt for every 95 amperes; the other to carry a current of 400 amperes, and to raise the pressure 1 volt for every 55 amperes.

The Chappe Telegraph.—Thursday last week was fixed for the unveiling of a statue of Claude Chappe, the inventor of what was once known as the "French Telegraph"; the necessary funds having been subscribed by the French telegraph staff, and a site having been given by the Paris Municipality. The Chappe telegraph rendered considerable service, and created a good deal of excitement during the Napoleonic wars, and was, it is unnecessary to say, not an electric but a semaphore telegraph. In a little volume entitled "Histoire de la Télégraphie," published in 1824, M. Chappe l'Aîné gives the history of the subject from the earliest times, and urges the general use of semaphore telegraphy by the commercial world. Claude Chappe brought his system of telegraphy to the notice of the Assembly on Thursday evening, March 22, 1792, but it was not until April 4, 1793, that permission was granted to carry out experiments, the outcome of which was an order to erect a line from Paris to Lille, which was at work by the end of 1794. In 1798 the line was extended to Dunkerque, and in 1803 to Brussels, lines being run to Strasburg and to Brest in 1798, and to Milan in 1805. The Chappe apparatus consisted of a long narrow arm which could be revolved into any desired position, with two smaller arms at either end of it also capable of taking up different positions relative to the main arm; at night time five lamps mounted on gimbals rendered the positions of the arms visible. By means of this apparatus 196 different signals could be made. To connect Paris with Boulogne at the time Napoleon was meditating an invasion of England, huge two-arm semaphores, very similar to our present railway signals, were employed, powerful lamps with parabolic reflectors being used at night. The arms were 18ft. long by 2½ft. broad. The author makes merry over the English Admiralty telegraphs, which it must be admitted were very crude apparatus compared with that of Claude Chappe. The semaphore line from London to Portsmouth, which sent its last message on December 31, 1847, was, however, capable of a certain degree of celerity; under favourable circumstances, with all the operators ready, the Greenwich time ball signal could be sent along it and answered in ¾min.

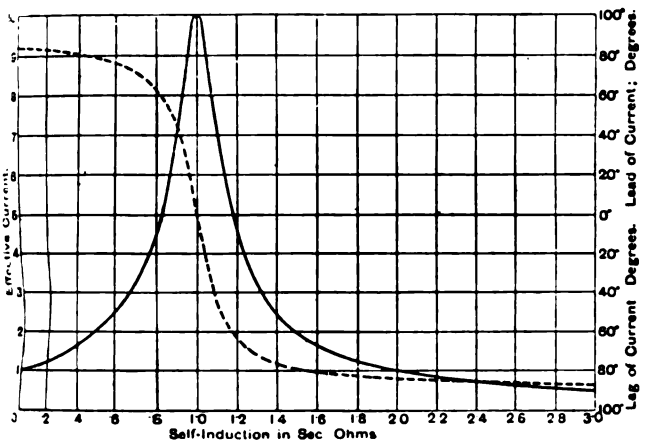
COIL AND CONDENSER IN SERIES.

BY PROF. PERRY, F.R.S. (AND H. BAYLY).

Instead of studying algebraic expressions, my students are in the habit of making numerical experiments. Many of their results are interesting, and although they cannot be looked upon by mathematicians as new, they are, I believe, new to the average student. The following is one of many examples which may be given. I neglect hysteresis in iron and eddy currents because the results are of the same character as if these phenomena were also considered. To take them into account it is only necessary to complicate the mathematical work in the manner indicated in my Paper on Choking Coils (Physical Society, March 11, 1892). A coil of resistance R and self-induction L is in series with a condenser of capacity K. If V



is the potential difference between the ends of this arrangement, whose resistance may be said to be $R + L\theta + \frac{1}{k\theta}$, the current C is

$$C = \frac{V}{R + L\theta + \frac{1}{K\theta}} \text{ or } \frac{K\theta V}{1 + RK\theta + LK\theta^2}$$

using θ to mean $\frac{d}{dt}$.

If V follows the law $V_0 \sin pt$ it is obvious (*see* the easy rule, Royal Society *Proceedings*, Vol. LI., p. 457, 1892) that the amplitude of the current is

$$\frac{K p V_0}{\sqrt{(1 - KLp^2)^2 + K^2 p^2 R^2}},$$

and the *lead* of the current is $\frac{\pi}{2} - \tan^{-1} \frac{RKp}{1 - LKp^2}$.

To study this, let R = 100 ohms, K = 1 microfarad, or $K = 10^{-6}$; let the *effective* voltage (or $V_0 \div \sqrt{2}$) be 1,000 volts; then for the following values of L we have the following effective currents and leads calculated by Mr. Bayly :—

L, in secohms.	Effective current, in amperes.	Lead of current, in degrees.	L, in secohms.	Effective current, in amperes.	Lead of current, in degrees.
0	0·995	84·28	1·05	8·944	- 26·57
0·1	1·110	83·67	1·1	7·071	- 45·0
0·2	1·240	82·87	1·2	4·472	- 63·43
0·3	1·414	81·87	1·3	3·162	- 71·57
0·4	1·644	80·53	1·4	2·425	- 75·97
0·5	1·961	78·67	1·5	1·961	- 78·67
0·6	2·425	75·97	1·6	1·644	- 80·53
0·7	3·162	71·57	1·7	1·414	- 81·87
0·8	4·472	63·43	1·8	1·240	- 82·87
0·9	7·071	45·0	1·9	1·110	- 83·67
0·95	8·944	26·57	2·0	0·995	- 84·28
0·975	9·701	14·03	2·5	0·665	- 86·18
1·00	10·00	0	3·0	0·499	- 87·13
1·025	9·701	- 14·03			

These results have been plotted by Mr. Bayly. It is interesting to see how the current increases slowly at first, as self-induction is introduced, and then more rapidly, reaching a maximum when L = 1 secohm, and diminishing again exactly in the way in which it rose, and becoming less and less slowly as L is very great. The change of *lead* into *lag* is also very interesting.

The current is a maximum when $LKp^2 = 1$, and it is then the same as if we had no condenser and no self-induction—as if we had a mere non-inductive resistance R. It is interesting to note that this condition $LKp^2 = 1$ is the relation which would hold between L, K and p (neglecting the small resistance term) if the condenser K were sending surging currents through the circuit R, L, connecting its two coatings.

THE THEORY OF THE ELECTROMAGNET.*

BY DR. O. FRÖLICH.

The Theorem of Hopkinson and the Magnetic Circuit.—It is somewhat surprising that, even in recent works on electromagnetism, no attempt is made to unite the theories of Hopkinson and Kapp, or to connect Hopkinson's theorem with the supposition of a magnetic circuit. We give this connection in the following.

Hopkinson, as well as Kapp, put the ampere-turns of the electromagnet equal to a sum of terms, each of which terms corresponds to a part of the electromagnet. If we denote the ampere-turns by MJ, the number of the lines of magnetic force in the air-gap by K, the length of a part of the electromagnet by L, the section by Q, Hopkinson's function by f, the coefficient of leakage by c, and if the indices 1, 2, &c., correspond to the different parts of the electromagnet (no index to the air-gap), Hopkinson's theorem is the following :—

$$\frac{4\pi}{10} MJ = L\frac{K}{Q} + L_1 f\left(\frac{c_1 K}{Q_1}\right) + L_2 f\left(\frac{c_2 K}{Q_2}\right) + \ldots ;$$

and if we denote by ϕ the function of saturation introduced by Kapp, by w the specific magnetic resistance of the air, by $\sigma_m = \frac{c_m K}{K'_m}$ the saturation, K'_m being the maximum of lines of force attainable by the part m, Kapp's equation will be

$$\frac{4\pi}{10} MJ = \frac{4\pi}{10} w L \frac{K}{Q} + L_1 \frac{c_1 K}{Q_1} \phi(\sigma_1) + L_2 \frac{c_2 K}{Q_2} \phi(\sigma_2) + \ldots$$

Each term in one equation must be equal to the corresponding term in the other equation; consequently, we have

$$f\left(\frac{cK}{Q}\right) = \frac{cK}{Q}\phi(\sigma) = \frac{cK}{Q}\phi\left(\frac{cK}{K'}\right),$$

and for the air, $\frac{4\pi}{10} w = 1$.

Hence it is clear that Hopkinson's theorem harmonises with the supposition of a magnetic circuit, and can be deduced from it, and that the theorems of Hopkinson and Kapp are identical.

Hopkinson's function is equal to the magnetic tension of the unit of length in a piece of iron; his theorem tells us that in a closed magnetic circuit the magnetomotive force is equal to the sum of the magnetic tensions at the ends of the different pieces.

Kapp's theorem corresponds to Ohm's law, if there is no leakage, and to Kirchhoff's second law, $\Sigma E = \Sigma JW$, if there is leakage; while Kirchhoff's first law, $\Sigma J = \sigma$, when applied to magnetic circuits, is a matter of course.

Kapp's function is in a simple way connected to Hopkinson's function; but the form

$$\frac{\text{tang}\frac{\pi}{2}\sigma}{\frac{\pi}{2}\sigma}$$

given by Kapp, does not agree with the observations.

Formulæ for the Functions of Hopkinson and Kapp.—Kennelly stated that the magnetic resistance, $\frac{mi}{k}$, of iron is a linear function of the ampere-turns, mi, except in the

* Abstract from the *Elektrotechnische Zeitschrift*, 1893, No. 25ff.

Digitized by Google

beginning of the curve. If we turn this observation into a formula representing the whole curve, we obtain

$$\frac{ni}{k} = a + \beta n i - \frac{\gamma}{\delta + ni}$$

where $n = \frac{4\pi}{10} m$; k being the number of the lines of force in a piece of iron of the unit of length and of the unit of section.

This formula can be employed in finding forms for Hopkinson's and Kapp's functions. First we observe that $\frac{1}{\beta} = k'$, the maximum of lines of force and ni depends only of the form, $\frac{1}{k} - \frac{1}{k'}$. Therefore, we introduce, as affecting the argument, the *rate of saturation*,

$$\lambda = \frac{k}{k' - k} = \frac{1}{\frac{k'}{k} - 1}$$

By this change we obtain more simplicity and natural meaning in the formulæ; in wrought iron, for instance, the ampere-turns are almost exactly proportional to the rate of saturation. We derive the following formulæ; for Hopkinson's function:—

$$ni = \frac{1}{2}(ak'\lambda - \delta) + \frac{1}{2}(ak'\lambda + \delta)\sqrt{1 - 4\frac{\gamma k'\lambda}{(ak'\lambda + \delta)^2}},$$

or

$$ni = ak'\lambda \left\{ 1 - \frac{\gamma}{a^2 k'} \frac{1}{\lambda + \frac{\delta}{ak'}} - \frac{\gamma^2}{a^4 k'^2} \frac{\lambda}{\left(\lambda + \frac{\delta}{ak'}\right)^3} - \ldots \right\}$$

and for Kapp's function:

$$\frac{ni}{k} = a(1+\lambda) \left\{ 1 - \frac{\gamma}{a^2 k'} \frac{1}{\lambda + \frac{\delta}{ak'}} - \frac{\gamma^2}{a^4 k'^2} \frac{\lambda}{\left(\lambda + \frac{\delta}{ak'}\right)^3} - \ldots \right\}$$

These formulæ agree with the middle curves observed by Hopkinson for wrought and cast iron, partly with sufficient, partly with high exactitude, and from the beginning to the end.

If we ask only for sufficient exactitude between the ordinary limits of saturation, omitting very low and very high saturations, the following most simple formula can be used:

$$\frac{ni}{k} = \rho^0 + \rho' \lambda = \rho^0 + \rho' \frac{k}{k' - k}.$$

Formula for the Electromagnet.—Taking the last formula representing the magnetic resistance of iron, we obtain for the electromagnet:

$$\frac{NJ}{K} = A_0 + A_1 \frac{K}{K_1 - K} + A_2 \frac{K}{K_2 - K} + \ldots \ldots$$

where $\frac{NJ}{K}$ is the magnetic resistance of the electromagnet, A_0 the initial magnetic resistance (air and iron) the indices 1, 2, &c., correspond to the different parts, and K_1, K_2, &c., are the maxima of lines of force, reduced by considering the leakage; all coefficients can be calculated from dimensions and magnetical qualities of the different sorts of iron.

If all parts have the same section and the same iron, we have simply

$$\frac{NJ}{K} = P_0 + P_1 \frac{K}{K' - K}.$$

But also all other electromagnets, as far as the technical practice goes, can be made to obey to this formula; the coefficients P_0, P_1, K' may be calculated by the dimensions and the properties of the different sorts of iron, but also by observations taken on the electromagnet.

The formula I formerly used for the electromagnet,

$$K = K' \frac{NJ}{P_0 K' + NJ},$$

is a special case of the equation given above, viz., if $P_0 = P_1$. Therefore, the general formula covers not only the numerous cases in which my older formula agrees with the facts, but also the cases where the older formula did not agree, for instance, in the dynamo machines examined and graphically calculated by Hopkinson in his known Paper.

In the article in the *Elektrotechnische Zeitschrift*, cited above, from which these lines are an abstract, there are further given a rule for the construction of electromagnets and a new mode of calculating the loss of energy caused by hysteresis.

THE DURATION OF THE DISCHARGES OF INDUCTION COILS.*

BY H. LEWIS JONES, M.D.

In the course of an investigation into some of the properties of medical induction coils I had occasion to set up an apparatus for counting the rate of vibration of their contact breakers, and so obtained the accompanying tracings, which may be of interest to your readers, because they seem to show that the secondary discharges of induction coils are not so brief as is

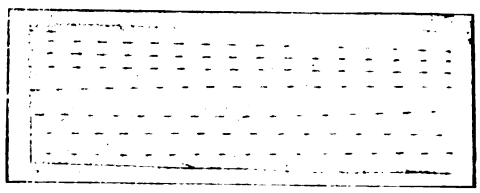


FIG. 1.—Electric Light ~ 100. Length of diagram = one-seventh Second.

generally supposed. For a particular coil Blaserna worked out the times of 0·000485 second and 0·000275 second as the duration of the make (inverse) and break (direct) discharges, and these figures are usually taken as showing that the discharges are of extremely short duration. The coil used is 7in. long and $2\frac{2}{3}$in. in diameter. Core small, $\frac{3}{4}$in. in diameter; primary

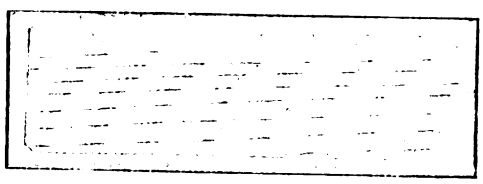

FIG. 2.—"Break" Discharges of Coil. Length of diagram = one-seventh Second.

turns 100, secondary 8,000 approximately; resistance of secondary 2,750 ohms, wound in two sections, paraffin insulated; weight of hammer, 300 grains; spring of stiff brass, $1\frac{1}{2}$in. long, $\frac{1}{2}$in. broad. Contact breaker screw close up to head of hammer, which, therefore, rebounds at once after contact, 52-55 times per second. With 4 volts and 2 amperes, gives 1in. sparks. Condenser the usual size as fitted.

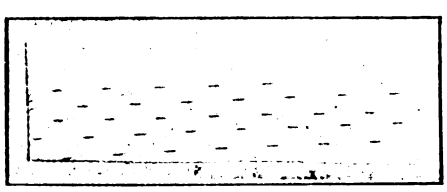

FIG. 3.—"Make" of Coil. Length of diagram = one-seventh Second.

The tracings (Figs. 1, 2, and 3) were taken upon a small revolving drum of metal covered with a strip of blotting paper wetted with starch paste containing iodide of potassium; the liberation of iodine at the positive pole strikes a dark blue colour with the starch. This reaction is much more sensitive than that of the ferrocyanide of potassium papers used in Bain's chemical printing telegraph. The drum was fixed upon

* Towards the expenses of this research a grant was made by the British Medical Association, on the recommendation of the Scientific Grants Committee of the Association

Digitized by Google

the axle of a small electromotor, which was joined to a Young's speed indicator (Fig. 4). One terminal of the secondary coil was connected to the rotating drum, and the other to a fine platinum needle which was held against the paper by the hand and was moved from end to end of the revolving drum. The needle was bent near the end into an acute angle or elbow; this was the part used to make contact with the drum, as the point was found to scratch the soft paper. The marks made by the bent elbow of the needle were not at all elongated until the recording surface was made to move, so the shape of the markings is not due to the shape of the surface of the needle. In this way a succession of streaks and intervals was drawn in a spiral upon the cylinder. The paper was taken off the drum and the tracings were photographed at once, as the marks are very fugitive. The figures represent the strips of paper used, photographed to half-scale.*

For purposes of comparison a trace was taken from the alternating electric lighting current. This is shown in Fig. 1. Fig. 2 shows the "break" discharges (positive pole) of the secondary of an induction coil capable of giving 1in. sparks. Fig. 3 shows the "make" discharges (positive pole) of the same coil, the direction of current in the primary having been reversed. The strips are to be read from right to left, beginning at the right hand top corner.

The speed of rotation recorded was seven revolutions per second; the circumference of the drum 4½in.; the velocity of the surface 31½in. per second.

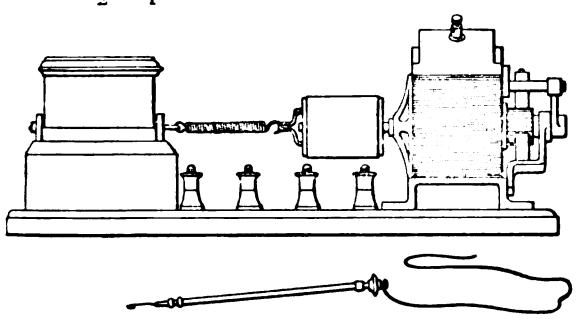

FIG. 4.—Motor, Revolving Drum, and Counter.

The rate of vibration of the contact breaker works out at 50 to 55 a second; and the rate of alternation of the electric lighting current at 112, the nominal rate of the latter being 100, I believe. The difference between these two figures is probably due to error in the indications of the speed indicator, which is a little difficult to read exactly, but it may show that the alternator at the central station was running a trifle faster than usual on the morning when the trace was taken. On another trial the rate came out at 105. Several tracings were taken on each occasion, and on each of those occasions the several traces agreed among themselves.

Measurement of the photographed tracings gives the mean duration of the discharges as follows:—

Break	0·0134 second.
Make	0·0046 „

The dotted marks at the top of Fig. 2 were caused by sparks passing though the air to the paper. It is interesting to note that they are not elongated or drawn out. The other marks are very long, and also taper off in a significant way; but no sign of this tapering appearance can be seen in Fig. 3.

The intervals in Fig. 1 (dynamo current) are longer than the marks; and from this we may reasonably infer that the method of recording does not exaggerate the length of the discharge, but rather tends to reduce its apparent duration. The resistance of the damp paper varies a good deal, but its average is rather more than 1,000 ohms.

When the make-and-break tracings are combined, and this can be done very simply by superposing their photographic negatives, it is clear that the intervals which correspond to the periods of no current in the secondary coil are very short indeed; at a rough estimate about 0·001 second, or even less in a total period of 0·019 second. At first I assumed that the short marks must be "break" discharges, and the long ones "make" discharges, but further experiments showed that this was not the case.

By substituting a mercury break for the vibrating spring contact-breaker it is possible to get single discharges, the primary circuit being made and broken by hand. When these single discharges are recorded upon the moving surface it is found that the "make" tracing does not exhibit the abrupt short character, shown in Fig. 3, but is longer and tapers away like the "break" discharges of Fig. 2. This led me to suppose that the "make" discharge was cut short by the next succeeding "break" discharge, and in order to settle this point a tracing was taken with two needles at once, one for each pole; it was then clear that the break discharge followed closely upon the make discharge without any perceptible interval at all. The character of the tracing given by both poles writing side by side (Fig. 5) is interesting. It was drawn by hand on a slip of paper, and gives a good general idea of the relations in time of the make and break discharges. It also explained why the "make" discharges had a shorter duration than the break. No doubt the character of the tracings depends a good deal upon the contact-breaker used. Some of these make a large excursion and leave the primary circuit open for a comparatively long time, while with others the primary is kept closed for a comparatively long time before it is broken again. The contact-breaker of the coil used in these experiments has a short and stiff spring, and makes very brief contacts.

The tracings of Fig. 2 show that the current at break of an induction coil discharging through a resistance of about 1,000 ohms may last as long as one-eightieth of a second. The shorter duration of the make discharge in the coil used is due to the fact that it is cut short by the establishment of a "break" current in the opposite direction.

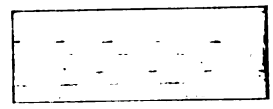

FIG. 5.—"Make" and "Break" (Positive) Discharges. To be read from left to right.

No sign of oscillation, or more correctly, no sign of alternation, can be seen in these tracings. In *The Electrician* for December 25, 1891, is an abstract of a Paper on the Induction Coil, by M. Colley, with figures of vacuum tube discharges as seen in a rapidly revolving mirror, and with curves to represent the oscillations of the discharge; though showing large oscillations, the curves do not show alternations, or changes of sign. If such had been present in my experiments the tracings should have shown them as gaps in the length of each small mark.

I should have been glad to supplement this communication with some notes on the effect on the tracings of putting a vacuum tube in the circuit; but I have not yet been able to get any satisfactory results; for the vacuum tube diminishes the current so greatly that the tracings become very faint, and the iodide of potassium paper sometimes behaves capriciously; however, a vacuum tube does seem to shorten the duration of the discharge considerably.

Tracings of smaller medical coils are essentially the same as those of the one used, the main difference is that the make marks are longer, if the contact breaker is less rigid and more springy.

* No. 3 was reduced a little too much in the camera.

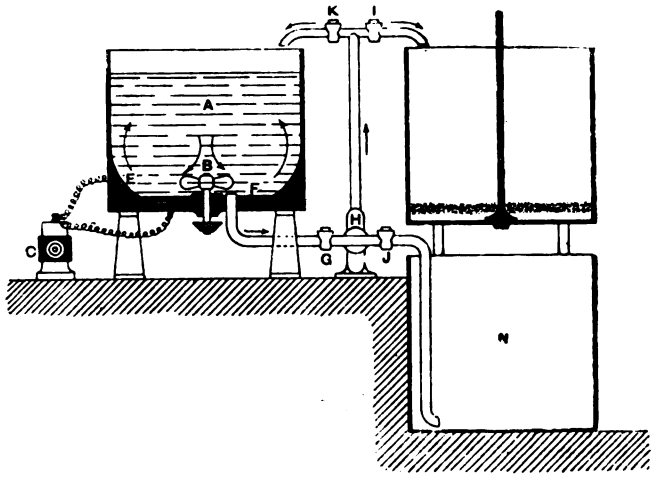
THE ELECTROLYTIC EXTRACTION OF GOLD.

A Paper was recently read by Mr. J. B. Hannay, at the Institution of Mining and Metallurgy, upon a method which he has brought out for the extraction of gold from various states of ore by means of an electric current. Since the reading of this Paper we have had an opportunity to examine the extraction plant and the working of the process. Briefly stated, the principle of the process is this:—The combination of an electrolysis of a gold cyanide with the amalgamation of metallic

Digitized by Google

gold; that is to say, the process consists in the addition to the ordinary mechanical washing and amalgamation of an auxiliary electro-chemical process, whereby the gold which is not directly amalgamated out is dissolved in a soluble cyanide, such as potassium cyanide, and is subsequently deposited on the mercury cathode from the electrolytic salt of gold thus formed. The process is essentially two-fold, and on this account it is claimed that it will ensure a more perfect extraction of gold than in the simple amalgam process. As an example of the yield of gold by this electro-cyanide process, we may quote the figures given in the case of the Maritoto ore by Mr. Fred. Claudet. The assay of this ore indicated 12oz. 5dwt. of gold per ton, and subjection to the process we have described gave a yield of 11oz. 13dwt. 12gr. per ton, or 95·3 per cent.

The annexed diagram shows the general arrangement of the reducing plant. It consists of a wooden vat, A, fitted all round its sides near the bottom with a number of carbon plates, E, forming the anode. A mercury bath, F, at the bottom of the vat forms the cathode. Dilute aqueous solution of potassium cyanide is poured into the vat, and the ore, which has previously been crushed, but not roasted, is added. The thick, muddy liquid thus formed is kept in circulation by the mechanically propelled screw, B. An electrolysing current is generated by the small dynamo, C. The ore circulates in the



Vertical Section of Extraction Plant.

direction of the arrows, with the result that the free gold is directly amalgamated out, while the refractory gold ore is dissolved by the cyanide, forming a double cyanide of gold and potassium. This double cyanide is very shortly reduced to metallic gold and the simple cyanide of potassium, by the electric current. Thus, it will be seen that the process is cyclic in its action; the limited quantity of cyanide serving to reduce an unlimited amount of ore. In from two to six hours the charge has been exhausted. The valves G and I are opened; and the centrifugal pump, H, is set in action, transferring the liquid from the working vat, A, to the filtering vat, L. Here the liquid cyanide filters into the receiver, N, while the sludge is retained in L. To operate on another charge of ore, it is only necessary to close the valves, G and I, and to open J and K, when the filtered cyanide of potassium will be returned to the working vat, and the whole cycle of operations may be repeated. It should be mentioned that the earliest patents, under which Mr. Hannay is working his process, date back to 1886.

REPORT OF THE JOINT COMMITTEE ON ELECTRIC POWERS (PROTECTIVE CLAUSES).

The Committee have taken evidence from Sir Courtenay Boyle, K.C.B., from Mr. Preece (Engineer-in-Chief and Electrician to the Post Office), from Major Cardew (Electrical Adviser to the Board of Trade, and the Astronomer Royal. Counsel appeared before them on behalf of (1) The National Telephone Company; (2) The Railway Companies; (3) Electric Tramway Companies and Electric Underground Railway Companies; (4) Electric Lighting Companies; (5) Municipal Corporations, England and Scotland; (6) Tramway Institute of Great Britain and Ireland; and (7) Gas and Water Companies. Her Majesty's Postmaster-General was also represented, but not by Counsel.

The Committee have heard all the witnesses tendered by the several parties, and have agreed upon the following Clause, to be inserted in all Bills and Provisional Orders which authorise the Undertakers, other than Electric Lighting Undertakers, to use large electric currents, viz.:—

CLAUSE

To be inserted in all Bills and Provisional Orders which authorise any company, corporation, or person, collectively referred to as "the Undertakers," to use larger electric currents for other than electric lighting purposes. (Some modifications of form may be required to meet the circumstances of particular cases.)

(1.) The Undertakers shall, in the use of electric power under the provisions of this Act [Order], employ either insulated returns or uninsulated metallic returns of low resistance. [This clause not to apply in the case of railways, tramways, or tramroads in which the motive-power is entirely self-contained.]

(2.) The Undertakers shall take all reasonable precautions in constructing, placing, and maintaining their electric lines and circuits, and other works of all descriptions, and also in working their undertaking so as not injuriously to affect, by fusion or electrolytic action, any gas or water pipes, or other metallic pipes, structures, or substances.

(3.) The exercise of the powers by this Act [Order] conferred with respect to the use of electric power, shall be subject to the regulations set forth in the Schedule to this Act [Order], and to any regulations which may be added thereto or substituted therefor, respectively, by any order which the Board of Trade may, and which they are hereby empowered to make from time to time, as or when they may think fit, for regulating the employment of insulated returns or of uninsulated metallic returns of low resistance, for preventing fusion or injurious electrolytic action of or on gas or water pipes, or other metallic pipes, structures, or substances, and for minimising, as far as is reasonably practicable, injurious interference with the electric wires, lines, and apparatus of other parties and the currents therein, whether such lines do or do not use the earth as a return.

(4.) The Undertakers using electric power contrary to the provisions of this Act [Order], or to any of the regulations set forth in the Schedule to this Act [Order], or to any regulation added thereto or substituted therefor by any order made by the Board of Trade under the authority of this Act [Order], shall, for every such offence, be subject to a penalty not exceeding *ten* pounds, and also in the case of a continuing offence to a further penalty not exceeding *five* pounds for every day during which such offence continues after conviction thereof: Provided always, that, whether any such penalty has been recovered or not, the Board of Trade, in case in their opinion the Undertakers in the use of electric power under the authority of this Act [Order] have made default in complying with the provisions of this Act [Order], or with any of the regulations set forth in the Schedule to this Act [Order], or with any regulation which may have been added thereto or substituted therefor as aforesaid, may by order direct the Undertakers to cease to use electric power, and thereupon the Undertakers shall cease to use electric power, and shall not again use the same, unless with the authority of the Board of Trade, and in every such case the Board of Trade shall make a special report to Parliament notifying the making of such order.

(5.) The Undertakers shall take all reasonable and proper precautions in constructing, placing, and maintaining their electric lines, circuits, and other works of any description, and in using their electric lines, circuits, and other works, so as not injuriously to interfere with the working of any wire, line, or apparatus, from time to time used for the purpose of transmitting electric power, or of telegraphic, telephonic, or electric signalling communication, or the currents in such wire, line, or apparatus. Provided always that the Undertakers shall be deemed to take all such reasonable and proper precautions as aforesaid, if and so long as they adopt and employ, at the option of the Undertakers, either such insulated returns or such uninsulated metallic returns of low resistance, and such other means of preventing injurious interference with the electric wires, lines, and apparatus of other parties, and the currents therein, as the Board of Trade shall direct, and in giving such directions the Board shall have regard to the expense involved, and to the effect thereof upon the commercial prospects of the Undertaking. Provided also that at the expiration of —— years from the passing of this Act [Order] nothing in this sub-section shall operate to give any right of action in respect of, or to protect any electric wires, lines, or apparatus, or the currents therein, unless in the construction, erection, maintaining, and working of such wires, lines, and apparatus, all reasonable and proper precautions, including the use of an insulated return, have been taken to prevent injurious interference therewith, and with the currents therein, by or from other electric currents. If any difference arises between the Undertakers and any other party with respect to anything in this sub-section contained, such difference shall, unless the parties otherwise agree, be determined by the Board of Trade, or at the option of the Board by an arbitrator to be appointed by the Board; and the costs of such determination shall be in the discretion of the Board, or of the arbitrator, as the case may be.

Digitized by Google

(6.) Nothing in this section shall apply to the use of any electric line, circuit, or work of any company, corporation, or person authorised by Act of Parliament, or Provisional Order confirmed by Parliament, to supply energy for electric lighting purposes, so far as such use is limited to such purposes.

The Committee have also agreed upon the following resolutions in the nature of recommendations, viz. :—

(1.) The Committee having regard to the evidence before them, are of opinion that it is not in the present state of electrical science to the interest of the public to insist upon electrical tramways using an insulated return conductor, and that such insistance would retard the development of electric traction.

(2.) The chief objections which have been urged before the Committee to an uninsulated return conductor are—first, the interference by leakage and induction with telephones; secondly, the interference by leakage and induction with railway signals; thirdly, the damage to systems of gas and water pipes by the action of leakage currents.

(3.) They are of opinion that the best known means of overcoming the first of these disturbances is by providing an insulated return conductor for the telephones, and they have the less hesitation in recommending this course, as the evidence shows that telephone construction is already tending in this direction, and that better results are secured to the public by the use of a twisted metallic circuit insulated entirely from the earth.

(4.) The second objection deserves serious consideration on account of the danger to the public; but the Committee are of opinion that the disturbance may be remedied at comparatively small expense by the adoption of an insulated metallic return by the railway companies.

(5.) They consider that, although electric tramway and electric railway companies should be allowed to use the wheels of carriages and the rails to complete the electric circuit, the currents should be produced and used in such a manner as to mitigate as far as is practicable any injurious effect to telephonic communication.

(6.) The Committee are of opinion that it is desirable in every way to facilitate the use of complete insulated metallic circuits for telephones, and for this end they recommend that statutory powers be granted enabling telephone undertakers to lay their wires underground.

(7.) The danger from fusion or electrolytic action appears to the Committee to have arisen from a faulty system of constructing electric tramways; and they are of opinion that it can be reduced by improved methods of construction so as to be practically negligible.

(8.) The Committee therefore recommend that the Board of Trade shall, in virtue of the powers to be conferred upon them by each Act or Order, make regulations to secure the best system of working electric tramways and railways, having regard to the expense involved by the carrying out of such regulations, and to the effect thereof upon the commercial prospects of the undertaking. The regulations to provide, *inter alia* :—

(a.) That a return conductor, if in contact with the ground, shall be of such section and resistance as to have no difference of potential sufficient to set up injurious leakage currents in the earth.

(b.) That, both with regard to the structure of the line and to the method of generation and use of the electrical current, everything shall be maintained up to the standard required by the Board of Trade; but, if the regulations are altered after the use of electric power on the line has been sanctioned, the Undertakers shall not be required to alter the structure or method of working of the line to conform to the more recent regulations, except for the public safety, or unless it shall be proved to the satisfaction of the Board of Trade that any system of metallic pipes or structures is being injured by the action of electricity escaping from the conductors, or for purposes other than public safety or injury to pipes or structures which the Board may think right, provided that the alterations do not in such last case cause substantial additional expenditure.

(c.) That all such electrical tests shall be applied to the line by the Undertakers as the Board of Trade may think necessary, and that a record of these tests shall be kept for the information of the Board of Trade.

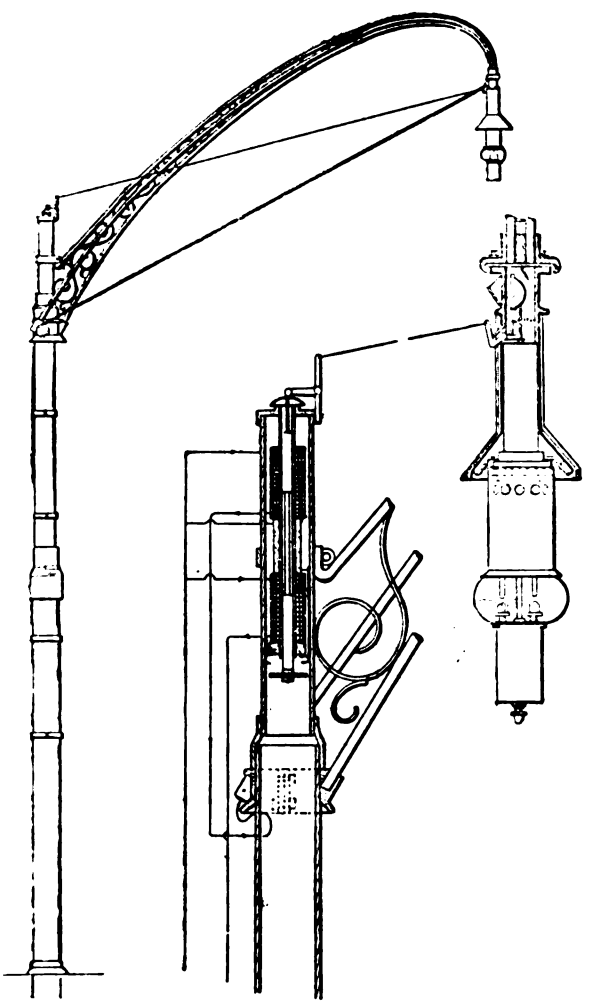
(d.) That the Board of Trade shall have all reasonable facilities for making any tests they may think necessary, in addition to those recorded by the Undertakers, to enable them to ensure the maintenance of satisfactory conditions.

(9.) That the Committee regards with apprehension a large extension of the system of overhead wires in crowded centres.

(10.) It appears to the Committee to be just that Undertakers proposing to use large currents should be required to give ample notice to those using small currents to enable them to protect themselves by insulation, and that with this view, and in reference to the clause agreed upon, a period of two years may fairly be allowed to telephone and telegraph companies from the date of the passing of any Act [Order].

A NEW STREET ARC LAMP AND POST.*

The accompanying illustration gives a clear idea of the new street arc lamp and support, invented and constructed by Rudolph M. Hunter, of Philadelphia, for the General Electric Company. The object is to reduce the weight of the lamp proper to a minimum to



enable the use of a light, graceful pole. In this lamp the weighty parts of the regulator are placed in the small tube on top of the vertical part of the post, as shown, while the lamp proper on the end of the arm contains only the carbon holders and means to feed the carbons. The regulator controls the carbons by means of a fine, invisible wire. The illustration shows clearly the construction of the lamp structure. The lamp proper is pulled into position by a light cord, and when in position it is coupled in circuit. The post is formed of tubes entirely, and is very light and strong. This lamp structure is designed to take the place of the numerous ungainly structures now disfiguring our streets. It has been exhibited in operation for some time in Philadelphia with entire satisfaction to the electric lighting fraternity.

THE ELECTRIC POWERS PROTECTIVE CLAUSES

The publication of the Report of the Joint Committee of Lords and Commons appointed to consider the question of the amount of protection which it would be to the public interest to afford in future to the National Telephone Company marks an epoch in the history of electric traction in the United Kingdom. Hitherto, in addition to the antipathy with which anything new is almost invariably regarded in this country, and to the undeniable unsightliness of the trolly, electric traction promoters have had to submit with the best grace they could to the onerous demands of the telephone interest. Henceforth the telephone is to have a fair field, but no favour. This is as it should be. It has never been suggested that the tractionists ought to be allowed to run their lines how and where they wished, nor denied that the working of an electric tramway would in all probability seriously disturb any single-wire telephone circuits that might be in its vicinity. The contention throughout has been that single-wire telephony was in any case quite unsuited to the conditions of urban exchange work, whilst electric traction, on the other hand, was a peculiarly effective solution of that which the Americans have aptly termed "the rapid transit problem." This being so it was thought preposterous that a bad system of telephony should be perpetuated and a valuable system of traction stamped out. To those therefore who have taken up this position the Report of the Joint Committee will be pleasant reading; since it is a victory for electric traction all

Digitized by Google

along the line, as will be made plain by a brief glance at the proposed Model Clause.

In future it will be incumbent upon electric tramways to employ low resistance metallic returns, insulated or uninsulated, and to take all reasonable precautions to prevent electrolytic action on gas and water pipes, and disturbance of telegraphic, telephonic, and railway signal circuits; the drawing up of detailed regulations, and the settling of what are "reasonable and proper precautions" being left, as usual, to the Board of Trade, whose official motto might well be *Hic et Ubique*. It is, however, Section 5 more than any other that entitles the Joint Committee to the gratitude of the oppressed motor man. Calling to mind, it may be, the tendency of Government departments to squeeze out the very life of an enterprise by a stout rope of red-tape regulations, the Board of Trade is bidden in laying down the law governing electric traction to "have regard to the expense involved, and to the effect thereof upon the commercial prospects of the undertaking." But something still better follows. In the next sentence it is laid down that after the lapse of a certain number of years (two years are recommended) from the passing of any tramway Bill, the owners of circuits affected by the working of an electric line shall be deemed to have no ground of complaint, unless all reasonable and proper precautions, "*including the use of an insulated return*," have been taken by them to prevent injurious interference. The final section exempts electric lighting companies from the operation of the clause; an exemption which may possibly prove but a qualified benefit. The energies of the Joint Committee were not, however, exhausted by the labour of drawing up a six-section clause, and the ten "resolutions in the nature of recommendations" which follow are scarcely less satisfactory reading than the clause itself. Eminent experts might prove to demonstration "that it is not in the present state of electrical science to the interest of the public to insist upon electrical tramways using an insulated return conductor, and that such insistence would retard the development of electric traction"; but who would believe them? When, however, the amalgamated wisdom of the two Houses of Parliament preaches such a doctrine, and follows it up by pointing out that the best way for the National Telephone Company to get over its troublesome ailments is for *it* to provide insulated returns, a course which the Committee have less hesitation in recommending, "as the evidence shows that telephone construction is already tending in this direction, and that better results are secured to the public by the use of a twisted metallic circuit insulated entirely from the earth," one need not be foolishly sanguine to anticipate that the matter is set at rest. On the other hand, the National Telephone Company will, we feel certain, fully appreciate the well-meant recommendation that every facility, including the grant of statutory powers, should be given it to take its wires underground.

The outcome of this inquiry being so entirely unambiguous, the interesting question now is, will it bear fruit or remain like the battle of Blenheim, nothing more than "a famous victory." Are we to expect an electric traction boom similar to that which is now raging in the United States with all the customary transatlantic concomitants, or shall we in this, as in so many other matters of the kind, "hasten slowly," and without fuss. The latter course is, we venture to think, the more probable, as it certainly is the more desirable. One step might well be taken, namely, the embodying of the results of the Joint Committee's labours in a short general Act, thus doing away with the necessity of fifty odd separate attempts to cancel the fifty odd clauses already secured by the National Telephone Company in fifty odd existing Bills.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 291.)

There is another process of treating cotton so as to produce a substance practically identical with Swan's parchmentised cotton thread, which possesses several great advantages over that process. It consists in dissolving cotton wool in a solution of chloride of zinc. The viscous solution produced by this means is squirted through a small hole into a vessel containing alcohol which causes it to set and harden. The great advantage of this method is that it produces a thread of amyloid of uniform diameter throughout, and which can be made of any size, according to the size of the hole through which it is squirted, and which requires no after process of cutting down by means of draw-plates. This is a very great advantage, as the wear and tear of the draw-plates is considerable and the cost of the process is saved. The process like all others requires great care if uniform results are to be achieved. The strength of the zinc chloride solution and the amount of cotton dissolved in it must be carefully regulated, as also the temperature at which it is kept while the cotton is dissolving. There are several difficulties met with. The cotton wool when put into the solution carries down with it a quantity of air, which, as the cotton dissolves, is seen in the form of bubbles all through the solution. The solution produced is of such a viscous nature that if left to itself these bubbles will remain wherever they happen to be, or at any rate they will rise so slowly that it would be a matter of weeks for them to reach the surface. In order to get rid of them the solution is filtered and at the same time heated under a vacuum. In this way most of them may be extracted. If they are not got rid of before the solution is squirted the very small ones will remain in the squirted thread while those which are of a size equal to, or larger than, the diameter of the nozzle of the squirt, will cause a break in the thread. The smallest air bubbles are the most troublesome as their presence may not be detected until the filament comes to be lighted up, when a bright spot will appear at the place where the bubble was located. It is also very important that there should be no lumps or parts of the solution which are thicker than the rest. When these occur and arrive at the nozzle of the squirt they may retard or stop the flow, and greater pressure has to be put upon the solution to force it through. As soon as the lump is through, the thinner portion of the solution following it will run too quickly. The result is that the thread is not uniform in diameter. Constant stirring during the dissolving will prevent the formation of lumps to a great extent. Messrs. Wynne and Powell, who patented this process in 1884, give the specific gravity of the zinc solution required as 1·8 and the temperature 100°C. The material finally requires thorough washing in alcohol or water. The drying may be done in the same way as already described for Swan's process.

Parchmentised paper was proposed by Swan before his cotton process. Ordinary hard paper without any chemical treatment has also been used. In all of the above processes the carbons are produced by the carbonisation of cellulose or some modification of it. All vegetable fibres contain cellulose, cotton being nearly pure cellulose, and many of them can be carbonised and made to do for lamp filaments either with or without any chemical treatment. Bass fibre, tampico fibre, and many kinds of grass have been tried. Some of them make very good lamps, but the great objection to all of them is the want of uniformity in size and composition. It is not likely that any of them will survive as commercial lamp filaments for this reason. Edison, of course, used bamboo, and with the aid of very ingenious machinery stamped out pieces of the required size. Specimens of the bamboo in the various stages of reducing to size were exhibited at the Crystal Palace Exhibition in 1882.

Many other substances have been tried. Of animal substances silk is undoubtedly the most successful, and may

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of re-publication reserved.

Digitized by Google

be carbonised without any previous chemical treatment. All animal substances, however, require special precautions during carbonisation.

The process of carbonisation consists in baking the carbonisable material at a very high temperature out of contact with the air. During the process the material will shrink and become hard and stiff and take permanently whatever shape it happens to be in at the time. Special arrangements have, therefore, to be made to control the shape of the filaments. The way this is accomplished will now be described, first of all in the case of long threads as produced by Swan's process.

For making plain horse-shoe filaments the thread is wound on carbon blocks or forms. Arrangements must, however, be made for the shrinkage. The material will shrink both in length and thickness, becoming about one-third smaller. If wound on a solid carbon block and then carbonised the thread will be broken in every turn or loop. Various methods of allowing for the shrinkage have been used. The one shown in the illustration (Fig. 6) is a good one.

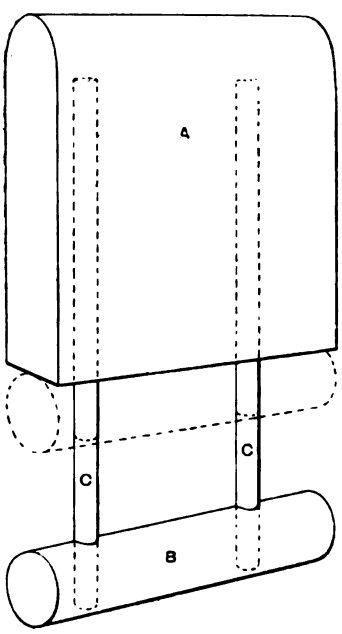

Fig. 6.

A is the carbon block with two holes about a quarter of an inch diameter drilled in it. B is a circular piece of carbon, the diameter of which is the same as the thickness of the block A. There are two holes drilled into B corresponding to those in A. At the top A should be well and smoothly rounded. A and B are connected together by sticks of hard wood C C, which may fit tightly in the holes into which they are driven home, reaching, therefore, to within half an inch or so of the top of the block. The thread is then wound round the block and end piece. It may either be wound on by hand, or the block may be clamped in a machine which will turn it round and wind it evenly, the machine feeding the block forward at the same time. When the block is filled it may be wrapped up in thin calico or paper, and it is then ready for packing in the crucible. By using the wooden sticks C C instead of a solid carbon block, the shrinkage of the thread is allowed for. The block is placed in the crucible with A uppermost, care being taken that it stands loosely and is not packed too tightly. As the process of carbonisation proceeds, the wood C C shrinks, and the block A descends at the same time that the thread contracts. By carefully regulating the temperature the thread is thus allowed to contract without being strained sufficiently to break it, but just enough to keep it perfectly straight. The length of the sticks C C is such that when the carbonisation is complete the block A will have sunk upon the end-piece B, the sticks being entirely enclosed in the holes. The illustration shows the block A and the end-piece B in position for winding on the thread. After carbonisation A and B are close together.

If it is desired to get a long filament into a comparatively short bulb, the filament may be bent round into a loop, as in the Swan lamp. This may be accomplished by simply using two of the round end pieces of the carbon blocks already described, joined together by the wooden sticks. The thread is then wound with a complete turn round the carbon at each end, the wooden sticks being long enough to allow of two filaments end to end. Instead of winding the thread straight down from one carbon to the other like the figure 0, it may be crossed like an 8. The use of solid carbon, however, is not good, owing to insufficient allowance for contraction in the loop. The thread will draw round the carbon in some degree as it shrinks, but only to a small extent, the result being that the filament is strained in the loop. This may be overcome by using split carbons instead of solid ones to wind the loop upon, as in Fig. 7.

A and B are the semi-circular carbons. C C the wooden sticks, which are smaller D D, where they pass through the holes in the carbons. Each piece A B has two other holes E E, into which are inserted short wooden sticks. In this way allowance is made for the shrinkage in the loop of the filaments as well as in the long sides.

In every process of lamp manufacture it is necessary to use the utmost care to prevent waste. Very slight differences in the ways of carrying out some of the processes may make all the difference in the result. Carbonisation is one such process. If the filaments are properly packed and handled, and the heat of the furnace is properly regulated, filaments made in the above manner may be obtained almost without loss, certainly with a breakage of not more than 2 or 3 per cent.

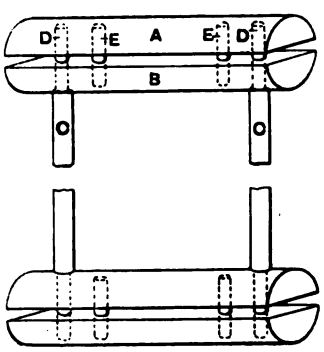

Fig. 7.

It is not sufficient, when the thread is wound on blocks in the way above described, to pack the blocks, either wrapped up or not in calico or paper, into a crucible and fill up all the remaining space with powdered carbon. The carbon powder will prevent the top part of the block from sinking during the shrinkage, and the result will be the breaking of most of the filaments. The blocks must be perfectly free to move as the shrinkage proceeds. The best way to insure this result is to use a carbon box inside the crucible. The box should be half an inch or so deeper inside than the length of the blocks when wound. A box may accommodate about ten blocks. The blocks are put in with the part A uppermost. Between each block is a thin plate of carbon about one-eighth of an inch thick. These plates slide easily in grooves in the sides of the box. By this means each block is in a separate chamber and is entirely free to move during the shrinkage. A carbon lid fits loosely on the top of the box. The whole carbon box is then put into a "plumbago" crucible of the same shape, but having a clearance of half an inch or so all round, and an inch higher than the lid of the box. The space between the box and the crucible is then filled up with powdered charcoal to the level of the top of the crucible, and the crucible lid is then put on and plastered down with fire-clay, care being taken to leave one or two small gaps in the fire-clay for the escape of the gases. If this is not done, the fire-clay may hold the lid so tightly that the gases cannot escape until a great pressure has been produced in the crucible, when the lid may be thrown violently off and the contents spoiled. No powdered charcoal is required in the carbon box, and the filaments cannot be

Digitized by Google

burnt at all by the small quantity of air left in the box. Before the temperature of red heat, which would be required to burn the filaments, is reached, most of the enclosed air has been driven out of the crucible by expansion. The gases produced by the charring of the filaments, the wood sticks and the calico wrapping have been coming off in such volume as to sweep out practically all the remaining air, so that by the time the filaments are hot enough to burn there is no air left in the box to burn them.

Flat filaments and those which are shaped before carbonisation, of course, require a different method of packing in the crucibles. Spirals and such like forms must be packed in carbon powder or plumbago as loosely as possible, so that they may retain their shape during the shrinkage. Such a method, however, is very costly, owing to the comparatively small number of filaments which can be accommodated in the crucible. Flat filaments may be packed between layers of paper or calico with a carbon block for a weight on the top. If calico is used it should be partially charred before using, as it shrinks during carbonisation more then most filament substances.

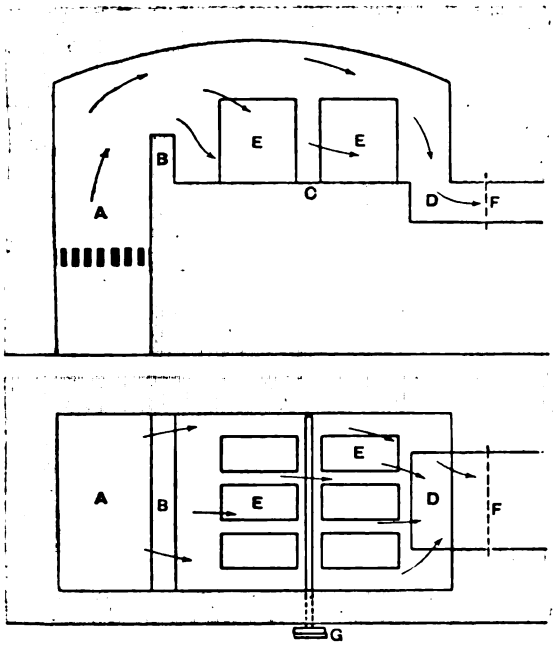

FIG. 8

Filaments of different material require different treatment during carbonisation. Some materials will allow of being heated much more rapidly than others, and some require a greater heat and more prolonged than others. Generally speaking, however, it may be said that the temperature should be raised very gradually and evenly, and should be raised as high as possible.

The construction of the furnace is also an important consideration. The fire must be in a separate chamber from the crucibles, which must not be liable to be knocked about when the fire is being stoked. It is well if the fire can be made to reach the crucibles evenly all round. This, however, is not important, provided that the temperature is at no time suddenly raised.

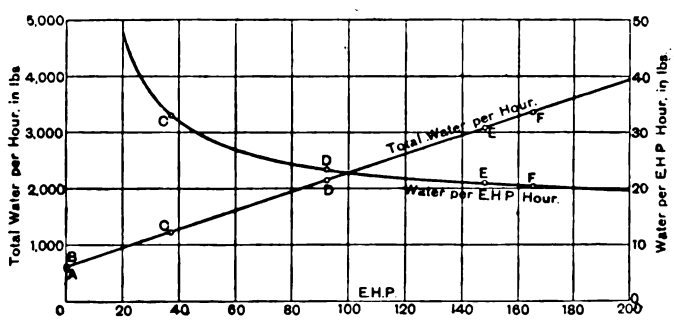
The illustration, Fig. 8, shows a form of furnace which works very well. The fire is in a chamber on the left. The hot gases pass over the "bridge," over and between the crucibles, and down through a flue into the chimney shaft.

A is the fire, B is a "bridge" of fire bricks, C is the floor of the chamber, D is the flue leading to the chimney shaft, E E are the crucibles, F is a damper in the flue D. The furnace door is made of fire-clay, and is bound together with iron. It can be raised and lowered by means of a chain and counterweight running over a pulley. The fire door can also be arranged in the same way. The furnace door has a small peephole in the centre, into which is fitted a fire-clay stopper. This hole also serves for the insertion of the pyrometer G, which is required during the first part of the process. The furnace must be substantially built with the best fire-clay bricks, and must be held together by iron tie rods and bands. The crucibles must be of the plumbago type, and the best to be had. The temperature they have to withstand is so great that they will only survive a few bakings.

(*To be continued.*)

THE PARSONS STEAM TURBINE.*

In accordance with the request of Messrs. C. A. Parsons and Co., I went to Newcastle last April, and spent two days in making a series of trials with one of Mr. Parsons's turbine-motors driving a continuous-current dynamo having an output of 150 units. The machine tested was, in external dimensions, almost exactly the same as that tested in August last by Prof. Ewing (see *The Electrician*, Vol. XXX., pp. 25 and 34); but by a rearrangement of the plates and discs its output has been very considerably increased. Its nominal maximum capacity is 150 units when working with 120lb. steam pressure, but it gave this output without apparent difficulty at 100lb. steam pressure, as will be seen below. As the motor has been so recently described, it is unnecessary that I should say anything as to its mechanical construction. The particular machine tested had six high-pressure single discs and one low-pressure double disc, the two sides of the latter being in parallel. It ran at about 4,500 revolutions per minute. The tests made were essentially directed to the determination of the quantity of steam used per electrical horse-power-hour by the motor at different loads. The water measurement was carried out by means of a little tank holding 370lb. of water (as checked by direct weighing). From this tank water was allowed to run into a somewhat larger one below it, from which the feed-pump



Feed-water Economy.

drew its supply. The feed-pump itself was worked by steam from a second boiler, which also supplied steam for the air-pumping engine. The boiler used for supplying steam to the motor was a small boiler of the locomotive type, capable of running only at 100lb. pressure. The boiler was so small for its work that there was no difficulty in keeping the feed practically continuous throughout the trials, and in keeping the water-level very steady. When running at full power the feed measuring tank lasted only eight minutes, so that it was easy to get a large number of points upon the water line in the diagram. The steam from the boiler passed through a series of superheating tubes on its way to the engine, these tubes being surrounded by the waste gases passing from the boiler to the chimney. In all the trials made, except where the engine was running light, it will be seen that there was a very considerable amount of superheating attained in this manner. It is to be regretted that it had not been found possible beforehand to make the boiler and its connections perfectly steam-tight. There were a not inconsiderable number of small leaks taking place, the total amount of which may quite well have considerably impaired the apparent economy of the motor. It was impossible for me to take these leaks, such as they were, in any way into account, and the water consumption which I give below therefore includes the whole of them, whatever they may have been. I need hardly point out that all these errors, without exception, were against the motor, and not in favour of it.

The dynamo which was used in the experiments had a continuous-current armature, not intended to take more than about 120 units.

* Abstract of a "Report on Trials of Parsons's Steam Turbine Dynamo and Alternator," by Prof. A. B. W. Kennedy, F.R.S.

Digitized by Google

This was the largest power for which the boiler could supply steam for more than a very short time, and this fact limited the maximum power at which any water measurements could be made. The whole of the electrical measurements were made by zero methods, using a Crompton potentiometer and standard Clark cells. A standard platinoid resistance of 0·001 ohm, which was sensibly free from temperature error for very much larger currents than those which I used, was employed in connection with the current measurements. The work done by the motor was taken up upon an artificial resistance of spiral wire divided into sections to suit the different powers required. During each trial the steam pressure and water-level were noted each time the measuring tank was emptied. The temperature of the steam, the vacuum, and the speed of the engine were noted at the same time or more often. The electrical measurements were made at regular intervals of five or ten minutes, according to the duration of the trial.

On the accompanying diagram are shown graphically the results of six trials of the motor and dynamo, two running light (excited only), one at about 28 kilowatts, one at about 70 kilowatts, one at about 110 kilowatts, and one at about 123 kilowattts. These are lettered respectively in the diagram with the letters from A to F. Experiment E, at about 110 kilowatts, is the one which I looked upon as the most important, as it was run at the largest power for which the steam could be kept up for any length of time. The actual duration of the run was just over two hours, in which time 17 tanks of water were used. It will be seen from the diagram how very uniform both the power and the water were during the whole of the run, and having obtained so many points on what appeared to be a straight line, it did not appear worth while to prolong the trial further. In this trial the mean output was at the rate of 110·8 kilowatts, or 148·5 E.H.P. The boiler pressure was 94·5lb. above the atmosphere, and the average amount of superheating was 66·7° F. The average vacuum shown by the gauge was 13·95lb. per square inch, the pressure of the atmosphere being equivalent to 30·3in. of mercury, or say to 14·86lb. per sq. in. The total water used per hour was 3,094lb., which is equivalent to 27·9lb. per kilowatt hour, or 20·8lb. per E.H.P. hour.

It is unnecessary that I should go over in detail the figures obtained upon the other tests ; they are given at full length in the annexed table. An examination of the observed point, shown on the accompanying diagram, shows that for all four experiments, C, D, E, and F, the water consumption was exceedingly regular throughout the whole duration of the test. I regret that it was not possible to carry on the highest power test (F) for more than three-quarters of an hour, but at this power the boiler was very uncomfortably forced, and the armature also was being somewhat hardly treated. It will be noted, however—and this forms by far the best test of the accuracy of the water measurements—that the four points in the diagram which represent the total water used per hour follow very exactly Willans's law—that is, they lie upon one straight line. In the two trials A and B (which were made on two different days), when the motor was running empty, circumstances rendered it only possible to use one tank full of water each time. There are, therefore, in these cases no such checks afforded as in the other tests by the straightness of the water-line throughout the whole duration of the trial. The two tests, however, agree with each other very well, and the two corresponding points, as will be seen, lie very nearly in their proper place at the commencement of the line which represents the total water used per hour.

The amount of superheating appeared to depend to a considerable extent, as was natural, upon the work which was being done by the boiler—that is to say, upon the amount and temperature of the chimney gases. Running empty, there was no superheating, or rather, the superheating had fallen to nothing by the time the steam reached the engine, close to which its temperature was measured. I have no doubt that there may have been, even then, a very considerable amount of superheating given to the steam after it had left the boiler. In trial C, which was really made immediately after trial D, the superheating commenced at the point at which it had reached during D, but it will be seen that after half-an-hour it fell to a much lower point, and remained there steadily. In trials D and E the amount of superheating rose from the beginning until it attained what appeared to be a more or less normal amount for the corresponding power. In trial F the temperature was still rising when other causes (which I have already mentioned) compelled me to stop the experiment. After all the other trials were ended I had the motor run up to give an output of 150 kilowatts, in order simply to see whether it could actually deal with this load. It was impossible to keep up steam for more than a few minutes under these conditions, and therefore no water measurement could be made ; but I found that with a steam pressure falling from 100lb. down to 90lb. the motor could drive the armature with an output of 152·6 kilowatts, apparently without the slightest trouble. The vacuum at this time was 13·8lb. per sq. in., and the steam temperature had only had time to reach 380° F. when the machine was shut down. The motor was running about 4,600 revolutions per minute, as will be seen from the table.

The following table gives the principal figures, totals, and means, &c., connected with the seven-trial runs :—

Experiments on a Parsons Steam Turbine Dynamo and Alternator, Heaton Works, April, 1892.

It is obviously not necessary for me to point out that the figures given in this table are figures of unusual excellence in economy, for they certainly rank among the best results hitherto obtained in the direct driving of dynamos by condensing machinery. The construction of the motors allows the advantage of superheating to be carried to the fullest extent, without any chance of injury to any parts of the machine, and no doubt this wise use of superheating has contributed to no small extent to the exceptionally good results which have been obtained. Since making the trials of which I have now summarised the results, I have been able to have special experiments made, with a view to determining to what extent the superheating has contributed to the result obtained. It is not necessary that I should give details as to these experiments, but their leading results may be summed up by saying that at about 35 E.H.P. the steam used without superheating was the same as with superheating, but that the difference gradually increased until at 100 E.H.P. it was about 8 per cent. The working of the boiler did not allow the non-superheating experiments to be carried farther than this, but if the same law of increase of economy held good up to the full power of the machine, its actual water consumption, as tested, must have been about 10 per cent. less than it would have been without superheating—a very notable difference. Of course this figure must be taken as only approximate, but it shows that even without superheating the motor would show very good results. I have only further to say that the engine worked throughout the trials without giving the slightest trouble in any way, either at low or at high loads. The throttle valve was full open in each case, and the engine ran upon its governor, which appeared to control it in a satisfactory manner.

THE ELECTROLYSIS OF STEAM.*

BY J. J. THOMSON, M.A., F.R.S.

(Concluded from page 293.)

Short Sparks.

I shall begin by describing the experiments with short sparks, *i.e.*, sparks from 1·5 to 4mm. long. Here the appearance of the spark shows all the characteristics of the "arc" discharge. The discharge passes as a thickish column with ill-defined edges, and when placed in a wind it is blown out to a broad flame-like appearance. For these short sparks or "arcs," as I prefer to call them, two very important laws were found to be true—

1. That within the limit of error of the experiments the volumes of the excesses of hydrogen in the one tube, and of oxygen in the other, which remain after the explosion of the mixed gases, are, respectively, equal to the volumes of the hydrogen and oxygen liberated in the water voltameter placed in series with the steam tube.

2. The excess of hydrogen appears in the tube which is in connection with the *positive* electrode, the excess of oxygen in the tube which is in connection with the *negative* electrode.

The following table contains the results of some measurements of the relation between the excesses of hydrogen and oxygen in the

* Abstract of Paper read before the Royal Society, March 9, 1893.

Digitized by Google

collecting tubes attached to the steam tubes and the quantity of hydrogen liberated in a water voltameter placed in series with the discharge tube. The ordinary vibrating break supplied with induction coils was used, except when the nature of the break is indicated :—

Spark length in millimetres.	Metal used for electrodes.	Excess of H in tube next + electrode.	Excess of O in tube next − electrode.	H in water voltameter.	Duration of experiment in minutes.

Medium Sparks.

When the spark length is greater than 4mm., the first of the preceding results ceases to hold. The second of these, that the hydrogen comes off at the positive electrode, remains true until the sparks are some 11mm. long ; but, instead of the hydrogen from the steam being equal to that from the water, it is, when the increase in the spark length is not too large, considerably greater. When the spark length has got to 8mm. this ratio begins to fall off very rapidly as the spark length increases, and we soon reach a spark length at which it seems almost a matter of chance whether hydrogen or oxygen appears in the collecting tube connected with the positive electrode.

When the sparks are at this critical length the kind of thing which happens is somewhat as follows:—For some time an excess of hydrogen (say) comes off in the tube next the positive electrode, and accumulates as the mixed gases are exploded ; then some slight change takes place in the action of the coil, and an excess of oxygen begins to appear ; this gradually wipes out the accumulation of hydrogen, and, if it goes on long enough, makes the residual gas in the tube entirely disappear ; then the oxygen begins to accumulate, only, however, to be wiped out later, when another change in the action of the coil has caused hydrogen to appear in excess in this tube. Thus, in this case, the residual gas in the tube does not, as before, steadily increase with the time of sparking, but is continually waxing and waning, sometimes being oxygen and sometimes hydrogen.

Long Sparks.

When the spark length is increased beyond the critical value the excess of hydrogen, instead of appearing as with shorter sparks at the positive electrode, changes over to the *negative ;* the excess of oxygen at the same time going over from the negative to the positive electrode. Thus the gases when the spark length is greater than its critical value appear at the same terminals, as they do when released from an ordinary electrolyte, instead of at the opposite terminals, as they do when the sparks are shorter.

The length of spark at which this reversal takes place depends, to a very great extent, upon the current sent through the steam ; the smaller the current the shorter the critical spark length. By diminishing the current by inserting a liquid resistance I reduced, on one occasion, the critical spark length from 11mm. to 8mm. This critical length, too, seems to depend upon a number of small differences not easily specified ; it will even vary greatly in the course of one afternoon, though apparently nothing has been changed. I have found, however, that this capriciousness disappears either altogether, or to a very great extent, if Leyden jars —very small ones will do—are attached to the terminals of the steam tube, or if an air break is placed in series with that tube. Under these circumstances the critical length will, if the same coil is used, remain constant from day to day.

It will be noticed that my results, when the length of the spark is greater than the critical length, agree with those obtained by Perrot and Ludeking, as these observers found that the hydrogen appeared at the negative, the oxygen at the positive, electrode. Ludeking worked with long sparks only, so that his results are quite in accordance with mine. In Perrot's experiments the spark length was about 6mm. I have never been able to reduce the critical length quite as low as this, even though I diminished the current to the magnitude of that used by Perrot ; I have, however, got it as low as 8mm., and it is probable that the critical length may not be governed entirely by the current.

I was not able to detect any change in the appearance of the spark as the spark length passed through the critical value. My observation on the connection between the appearance of the discharge and the electrode at which the excess of hydrogen appears may be summed up in the statement that when the discharge is plainly an arc the hydrogen appears at the positive electrode, and when the hydrogen appears at the negative electrode the discharge shows all the characteristics of a spark. However, before the spark length reaches its critical value the discharge looks much more like a spark than an arc.

With regard to the quantity of hydrogen liberated from the steam in comparison with that set free in the voltameter, I find that when the spark length is a few millimetres greater than the critical length the amount of hydrogen from the steam is very approximately the same as that in the voltameter. When the sparks are longer than 14mm. the amount of hydrogen from the steam was no longer equal to that from the voltameter. The results, however, were irregular, and, as mentioned before, there was a considerable quantity of nitrogen (?) mixed with the hydrogen and

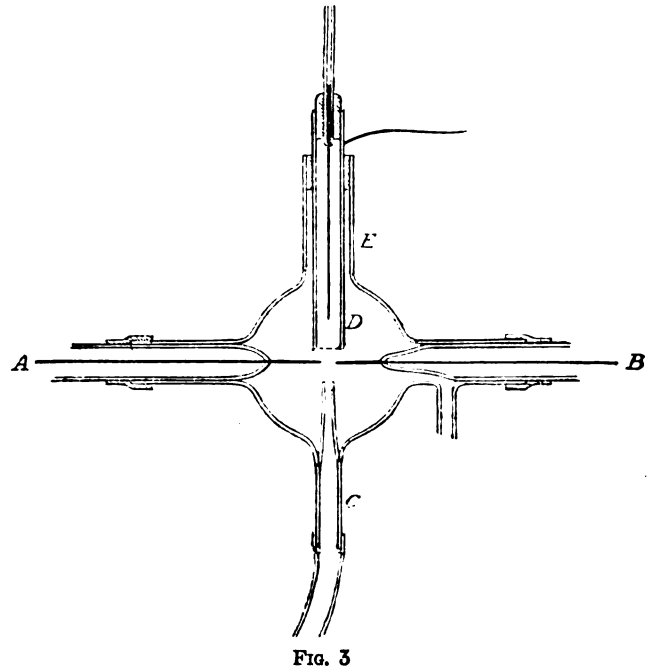

FIG. 3

oxygen. When the sparks are very much longer, say about 22mm., the electrode at which the hydrogen appears reverses again, *i.e.*, the hydrogen comes off at the positive electrode, just as it does when the sparks are very short. With these very long sparks the current is extremely small, and it takes several hours to liberate 1 c.c. of hydrogen in the voltameter. The proportion of hydrogen from the steam to that from the voltameter was with these long sparks too irregular to admit of any conclusions being drawn.

The preceding results show that in the electrolysis of steam, as in that of water, there is a very close connection between the amounts of hydrogen and oxygen liberated at the electrodes and the quantity of electricity which has passed through the steam, and that this relation for certain lengths of sparks is the same in steam as in electrolytes. There is, however, this remarkable difference between the electrolysis of steam and that of water, that whereas in the case of water the hydrogen always comes off at the negative, the oxygen at the positive electrode ; in the case of steam the hydrogen and oxygen come off sometimes at one terminal, sometimes at the other, according to the nature of the spark. The results obtained with the arc discharge, viz., that the oxygen appears at the negative electrode, the hydrogen at the positive, is what would happen if the oxygen in the arc had a positive charge, the hydrogen a negative one. As this is contrary to the commonly-received views of the electro-chemical properties of these gases, I endeavoured to see if I could obtain any other indications of this peculiarity. With this object I have made a series of experiments on the properties of various gases when the arc discharge passes through them. The apparatus used for these experiments is represented in Fig. 3. The arc discharge between the platinum terminals A B was produced by a large transformer, belonging to the Cavendish Laboratory, which transforms up in the ratio of 400

* In this experiment a slow mercury break making about four breaks per second was used.

† In these experiments large Leyden jars were attached to the electrodes.

Digitized by Google

to 1 ; an alternating current of about 35 amperes, making 80 alternations per second, was sent through the primary of this. A current of the gas under examination entered the discharge tube through the tube C, placed underneath the arc, and blew the gas in the neighbourhood of the arc against the platinum electrode E, which was connected to one quadrant of an electrometer, the other quadrant of which was connected to earth. To screen the electrode E from external electrical influence, it was enclosed in a platinum tube, D, the end of which was made of fine platinum wire gauze, which, though it served as a screen for electrostatic action, yet allowed the gases in the neighbourhood of the arc to pass through it. This tube was connected to earth. After passing out of the tube, the electrode E was attached to one end of a gutta-percha-covered wire wound round with tin-foil connected to the earth ; the other end of this wire was connected to the electrometer.

The experiments were of the following kind :—The quadrants of the electrometer were charged up by a battery ; the connection with the battery was then broken, and the rate of leak observed. When the arc was not passing, the insulation was practically perfect, the spot of light reflected from the mirror of the electrometer hardly moving appreciably in the course of three minutes. As soon, however, as the arc was started, and for as long as it continued, the insulation of the gas surrounding E in many cases completely gave way. There were, however, some remarkable exceptions to this, which we now proceed to consider.

Oxygen.

We shall begin by considering the case when a well-developed arc passes through oxygen :—

1. When the electrode E is charged negatively. In this case it loses its charge very rapidly ; it does not, however, remain uncharged, but acquires a positive charge, increasing until the electrode E has acquired a potential V. V depends greatly on the size of the arc and the proximity of the electrode ; in many of my experiments it was from 10 to 12 volts.

2. When the electrode is charged positively. If the potential is very high the electrode leaks until the potential sinks to V ; after reaching this potential the leak stops, and the gas seems to insulate as well as when no discharge is passing through it. If the potential to which E is initially raised is less than V (a particular case being when the electrode is entirely without charge to begin with) the positive charge increases until the potential of E rises to V.

If the spark length is increased until the discharge passes as a spark then the electrode leaked slowly, whether charged positively or negatively ; the leak in this case is, however, very small compared to that which exists when the discharge passes as an arc.

Hydrogen.

When the *arc* discharge passes through hydrogen the electrode E always leaks when it is charged positively ; it does not merely lose its positive charge, but acquires a negative one, its potential falling to U, where U is a quantity that depends on the size of the arc, and on its proximity to the electrode ; in my experiments five or six volts was a common value for U. If the electrode E is initially uncharged, it acquires a negative charge, the potential falling to U while if it is initially charged negatively it leaks if the negative potential is greater than U, until the negative potential falls to U, when no further leak occurs ; if the negative potential is less than U, the negative charge on the electrode increases until the potential becomes equal to U, when it remains steady.

These experiments show that the oxygen in or near the arc discharges a negatively electrified body, but not a positively electrified one, while the hydrogen in or near the arc discharges a positively electrified body, but not a negatively electrified one. And also that an unchanged electrode becomes positively electrified in the oxygen, negatively electrified in the hydrogen.

I next endeavoured to see if this charging up of the electrodes is due to an electrification developed by the contact of the gas in the arc with the electrode, or whether this gas behaved as if it possessed an independent charge of electricity. If the electrification is due to the contact of the gas with the electrode, then it ought to disappear when the electrode is covered with a layer of a non-conductor ; if, however, the gas in the arc behaves as if it were charged, then, even though the electrode is covered with a non-conductor, the electrostatic induction due to the charge on the gas ought to produce a deflection of the electrometer in the same direction as if the electrode were uncovered. I tried, therefore, the effect of covering the electrode with glass, with mica, with ebonite, and sulphur. I found that, in all these cases, the electrometer was deflected as long as the arc existed, and that the direction was in the direction corresponding to a positive change when the arc was in oxygen, and in that corresponding to a negative one when the arc was in hydrogen. The deflection, though not so large as when the electrode was bare, was quite unmistakable. It disappeared almost entirely as soon as the arc stopped.

These experiments show that the oxygen in the arc behaves as if it had a charge of positive electricity, while the hydrogen in the arc behaves as if it had a change of negative electricity.

The following explanation of the results of the experiments on the electrolysis of steam seems to be that which agrees best with the preceding investigation. When an electric discharge passes through a gas the properties of the gas in the neighbourhood of the line of discharge are modified. Thus, as Hittorf and Schuster have shown, the gas in the neighbourhood of the discharge is no longer an insulator, but can transmit a current under a very small potential difference. Faraday's remark, that when once a spark has passed through a gas the passage of another following it immediately afterwards is very much facilitated, is another example of the same thing. We have thus good reasons for believing that when a spark passes through a gas it produces a supply of a modification of the gas, whose conductivity is enormously greater than that of the original gas. I have shown (*Phil. Mag.*, November 1891) that the conductivity of this modified gas is comparable with that of strong solutions of electrolytes. When the discharges stops this modified gas goes back to its original condition. If now the discharges through the gas follow each other so rapidly that the modified gas produced by one discharge has not time to turn to its original condition before the next discharge passes, the successive discharges will pass through this modified gas. If, on the other hand, the gas has time to revert to its original condition before the next discharge passes, then the discharges pass through the unmodified gas ; we regard this as being accomplished by means of successive decompositions and recombinations of its molecules, analogous to those which, on Grotthus's theory of electrolysis, occur when a current passes through an electrolyte.

From this point of view, the explanation of the results of the experiments on the electrolysis of steam are very simple. The modified gas produced by the passage of the discharge through the steam consists of a mixture of hydrogen and oxygen, these gases being in the same condition as when the arc discharge passes through hydrogen and oxygen respectively, when, as we have seen, the hydrogen behaves as if it had a negative charge, the oxygen as if it had a positive one. Thus, in the case of the arc in steam, the oxygen, since it behaves as if it had a positive charge, will go to the negative, while the hydrogen, behaving as if it had a negative charge, will go to the positive electrode. We saw that this separation of the hydrogen and oxygen took place. The correspondence between the quantities of hydrogen and oxygen from the electrolysis of the steam and those liberated by the electrolysis of water shows that the charges on the atoms of the modified oxygen and hydrogen are the same in amount, but opposite in sign to those we ascribe to them in ordinary electrolytes.

PARLIAMENTARY INTELLIGENCE.

The Dublin Southern District Tramways Bill.

The Dublin Southern District Tramways Bill came before the Select Committee of the House of Commons, over which Mr. Samuel Hoare presided, on Friday last. The object of the Bill is to authorise the use of mechanical power in the working of the Dublin Southern District Tramways, and to enable the Company to acquire the undertaking of the Blackrock and Kingstown Tramways Company.

Mr. Crippe, Q.C., and Mr. J. D. Fitzgerald appeared for the promoters, and Mr. Pembroke Stephens, Q.C., and Mr. Clifford, for the petitioners against the Bill, the Dublin, Wicklow, and Wexford Railway Company.

Mr. CRIPPS, in opening the case for the promoters, said the point n dispute between the promoters and their opponents was a very narrow one. Really, the only point was what form of protective clause should be inserted in the Bill in order to ensure that no damage should be done to the Railway Company's railway signals by the use of electrical power along the tramway lines.

At this point a proof of the Joint Committee was produced, and

Mr. CRIPPS read the Model Clause. He would ask the Committee under these circumstances not to ask them to call expert witnesses at enormous cost and to go over the case again.

Mr. PEMBROKE STEPHENS said there were other points at issue besides that of the protective clauses. The petitioners urged that powers to work the tramways by mechanical or electrical power was in contravention of the express provisions in the Act authorising this tramway, the Act only being passed by Parliament under the provision that the tramway should be worked by horse-power. They futher submitted that it would be in contravention to the Order in Council of the Lord Lieutenant, and that the working of this tramway by electricity could not fail to inflict injury on the petitioners. This tramway ran absolutely parallel with the railway, almost touching at some points. He accepted the model clause as far as it went, but the main point was whether this Company should have electrical power or not.

Mr. CRIPPS said he would call evidence on that point. Mr. Spagnoletti and Mr. Alexander Siemens having been examined, Mr. PEMBROKE STEPHENS urged that if the Committee were going to pass the Bill, at least they should insure that there should be a proper local inquiry and

Digitized by Google

safeguard before anything was done, so as to prevent any mischief happening.

Mr. W. L. PAYNE (General Manager of the Dublin, Wicklow, and Wexford Railway Company) was then called. He said the wires by which the singles were worked would be parallel with and very close to the proposed overhead wires for the tramway. The tramway crossed the railway. They were in an exceptional position in Ireland in reference to the main block signal stations. The staff were under Witness's control, but the maintenance was taken charge of by the Post Office. He considered that the Model Clause did not in this case give the Railway Company sufficient protection. He thought that the proper maintenance of the Tramway Company's electrical system would depend to a great extent upon its financial position, and if that did not become better than it was at present, it would be a very bad look out. He thought it a great hardship that the Railway Company should not have an opportunity of being heard before the Board of Trade before the use of electricity was sanctioned upon this tramway.

Cross-examined, WITNESS said the block system on the Dublin, Wicklow and Wexford Railway was the best in the country.

Mr. LANGDON (Superintendent of the Electrical Department of the Midland Railway) gave scientific evidence with regard to electric traction, and said if they had a tramway worked by the electrical system they must have proper protection.

Mr. HARRISON (General Manager of the London and North-Western Railway Company) was called next, and said if he were responsible for the conduct of the Dublin Railway Company he should view the introduction of this electric tramway with the very greatest apprehension. If there were the slightest possibility of the smallest interruption with railway signals it would be a very serious matter.

Mr. CRIPPS replied on behalf of the promoters. Mr. CLAY (Solicitor to the Promoters) was then called to give formal proof of the uncontested portion of the preamble. After consultation with his colleagues, the CHAIRMAN announced that the Committee had decided that the preamble was proved, and they understood that model clauses would be put in the Bill.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 7, 1893.

Incandescent Lamp Litigation.—Another chapter in incandescent lamp litigation has been begun at Milwaukee (Wis.). The suit now being tried there is an application for an injunction against a small lamp company, but the real defendants, as in the St. Louis case, are the lamp manufacturers who are attempting to break up the General Electric Company's lamp monopoly. A great deal of bitterness is being shown in the present case, and counter charges of bribery and perjury are being made. The plaintiffs charge fraud and perjury in regard to the Goebel evidence, and the defendants charge bribery of Henry Goebel, jun. New points have been made by each side, and at the time of writing it is impossible to give any indication as to the final result.

Electric Traction Franchises.—The great expansion of electric traction has brought into strong relief the disgraceful state of municipal government in the United States, as well as the ease in which corrupt measures may be passed through our legislative bodies. In all of the larger cities electric traction is almost entirely in the hands of corrupt politicians, and many of our notorious political bosses are becoming opulent through their control of street railway franchises. In New Jersey recently a threat that the Governor would suspend certain officials was necessary to put an end to the free gift of valuable franchises. In Brooklyn, the mayor and aldermen were only prevented from being indicted by the grand jury by the discovery that a Bill had been passed by the legislature, putting the offence charged under the sole jurisdiction of police justices, who are tools of the ring. Altogether the seeking for franchises through electrical development has brought to light a state of political corruption that is disheartening. The only encouraging feature is that the leaders, almost to a man, are of foreign birth.

The Working of Lock Gates by Electricity.—The chief engineer of the Dominion canals states that tests of the applicability of electricity to the working of lock gates are being made on the Beauharnois Canal, and should they prove satisfactory, electrical appliances will be adopted in connection with the Canadian Canal at Sault Ste. Marie, water-power from the canal being used to generate the electricity. The result of the tests on the Beauharnois Canal will be known shortly.

CORRESPONDENCE.

MEASURING MAGNETIC FIELDS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The writer of the Note on "Measuring Magnetic Fields," which appeared in your issue of July 14th, appears to have been misled by the use there made of the symbol H.

Instead of making H denote the horizontal intensity of the earth's field, Mr. Russell uses it to represent the horizontal intensity of a magnetic field, where the effect of the earth's magnetism is interfered with by masses of iron or other disturbing elements, and where the lines of force can hardly be considered parallel relatively to a magnet but a few inches long. In such a field errors of very appreciable magnitude would be involved in a measurement made with an ordinary magnetometer, of which the needle is necessarily much larger than that used by my colleague.

I do not think Mr. Russell claims any theoretical advantage for the one he described over the tangent galvanometer method, but, in places where there are big masses of iron lying about, and currents of a magnitude generally measured on an ordinary ammeter are used, tangent galvanometers are not, as a rule, to be found, and the practical advantage of a method in which the only additional piece of apparatus required is an ordinary charm compass is a very distinct consideration.—Yours, &c.,

HUGH ERAT HARRISON.

Faraday House, Charing Cross-road, W.C.,
July, 18, 1893.

INSULATING WATER PIPES BY PAINTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the evidence given before the Committee on the Electrical Powers Protection clauses, Sir Frederick Bramwell mentioned that the paint on water pipes would act as an insulator. The following experiment will, I think, show that the value of such insulation is extremely small. In a water resistance consisting of two lead plates in a solution of sodium sulphate, one of the plates was painted with a paint much used for electrical purposes, consisting chiefly of bituminous compounds, and asserted to be an insulator. The surface painted was about $3\frac{1}{2}$ sq. ft. When perfectly dry it was coupled up to a dynamo giving a pressure of 60 volts, and a current of 100 amperes was obtained through the paint, the resistance of the cell being only slightly increased by the painting. This current was kept on for about 15 minutes, and on stopping the paint was found to be hardly damaged, the only part affected being the terminal where the current entered the cell. This shows that in the large area of a water pipe the paint would be absolutely useless in preventing the flow of electricity from the earth to the pipe, or *vice versâ*.—Yours, &c.,

University College, Liverpool. FRANCIS G. BAILEY.

[Our correspondent has hardly reproduced the conditions of actual practice, for he substitutes a strong salt in the solution in place of the soil, and uses a higher voltage than might in practice be expected to occur. It also appears that he neglected to prevent contact of the electrolyte with the negative pole, as corrosion at this part was observed. A similar test carried out on a hundred yards of pipes covered with Angus Smith composition, in damp soil, would be of considerable interest.—ED. *E.*]

USEFUL FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following simple rules will be found useful when a wire list is not at hand:

$$\sqrt{\text{current}} = 28 \times \text{diameter in inches.}$$

This is on the basis of 1,000 amperes per sq. in. for round copper wires.

$$\text{Resistance per mile} = \frac{0{\cdot}05617}{(\text{diameter in inches})^2}$$

Yours, &c., F. O. HUNT.

THE EASTBOURNE ELECTRIC LIGHT COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has just been directed to the speech of Mr. Denny Lane, M.A. (the President of the Incorporated Gas Institute), at the annual meeting of that body, recently held at Belfast, and also to his letter published in *Lightning* of July 6th, in both of which he refers to the Eastbourne Electric Light Company. I should not have noticed Mr. Lane's remarks had they been either just, generous, or in accordance with facts, but as they are neither and contain allegations against myself, I feel bound to notice them. At the outset I say most emphatically that neither the Directors of the Company nor myself have ever attempted to keep to ourselves or otherwise suppress or conceal the position or accounts of the Company, but for the information of Mr. Lane I propose to give the *facts* upon which his remarks and allegations are apparently founded.

The last annual meeting of the Company was held in February, and prior to the meeting the report and accounts were issued to the shareholders and debenture-holders, *and a copy thereof was sent to each of the five local journals, and also to the electric lighting journals for publication.* Before the holding of the meeting summaries of the report and accounts appeared in a number of publications, and there were several reporters present at the annual meeting, full reports of which were published. The Directors were, and are, proud of the position the Company has attained. It was the first established in England for the supply of electricity from a central station, and as the pioneer of electric lighting companies it has necessarily spent a large sum in experimental working, and its capital is thus somewhat larger than it would otherwise have been.

Some weeks subsequent to the annual meeting Mr. Hammond, the manager of the Eastbourne Gas Company, called upon me with reference to some business. In the course of conversation the Electric Light Company was referred to, and Mr. Hammond asked me if I had any objection to give him a copy of its last published accounts. I said, "None whatever;" and I added that a copy should be sent him in a few days as I had none at hand. I was not aware at the time of the approaching meeting of the Incorporated Gas Institute, or even of the existence of that august body, otherwise I might have drawn some inference as to the purpose for which the accounts were required. Being an extremely busy man, and having an unusually heavy pressure of work at the time, Mr. Hammond's desire to be supplied with a copy of the accounts for the moment escaped me, and before it recurred to my mind I was waited upon by Mr. Peters, a gentleman from the Gas Company's office, *demanding to be supplied under the provisions of the Companies Acts with a copy of the last annual accounts of the Company, for which Mr. Peters stated he was prepared to pay or tender me the usual fee, which he fixed at 1s.* I replied that I knew the Companies Acts pretty well, but I was not aware that any person had a right to *demand* a copy of the accounts; but I was quite prepared to give one. The demand was such an unusual one that I asked Mr. Peters if he sought to obtain the accounts for himself. He said "No." I then inquired if it was for the purposes of an appeal which my Company is prosecuting against its assessment. Mr. Peters replied "No." I then pressed him to tell me from whom the demand came, and after some hesitation he told me he had requisitioned me on behalf of Mr. Hammond (the manager of the Gas Company). I said, "I am astonished at this, as I have promised Mr. Hammond a copy of the accounts, and should have sent it; but," I added, "having regard to the course which has been pursued, I consider I am released from this promise." Before Mr. Peters left I said, "show me under what Section of the Companies Act Mr. Hammond demands the copy of the accounts, and he shall have it." The Section has never been pointed out to me, and I am now charged with refusing to *give* a copy of the balance-sheet to a ratepayer who has contributed his quota to the public lamps, and with a foolish attempt to conceal what could not be hidden. Self-respect alone dictated the only course I could pursue, and I leave your readers to judge whether Mr. Lane's allegation that there has been any attempt to conceal the position of the Company is either honest, honourable, or true.

Mr. Lane is correct in stating that this is the first year in which a dividend has been paid to the shareholders, but he endeavours to manipulate the figures of the balance-sheet so as to show that only £431 has resulted from last year's trading, including sums received for installation work and tuition fees. This is a fabrication. The total profit earned for the year ended December 31, 1892, was £1,746. 2s. 11d., of which £400 was written off for depreciation of plant and machinery, £1,074. 9s. 7d. was absorbed by the payment of interest at £5 per cent. upon the Company's debenture capital, a further sum of £73. 12s. 5d. was also paid for interest on mortgages and debentures redeemed, leaving a balance of £198. 0s. 11d., and with this and a balance earned upon the 1891 working after the payment of debenture interest, a dividend of £3 per cent. has been paid upon the Preference and Ordinary share capital of the Company. Mr. Lane ignored the debenture capital, upon which interest is regularly paid at £5 per cent. I assume debentures are (except, perhaps, in a technical sense) as much the capital of a company as share capital. Mr. Lane's figures are a miserable perversion of facts, and did he not attempt by his letter to justify the remarks contained in his speech, it would be charitable to suppose his brief perusal of the accounts had led him into error. But between the annual meeting of the institute and the date of his letter he had ample time to digest the figures. The fact is that after payment of all working expenses, and allowing for the two sums of £169 and £25, to which Mr. Lane alludes, my Company netted as the result of its operations for 1892 £1,552, or, to be accurate, £1,551. 13s. 9d. I question whether gas companies did better in their infancy.

I am somewhat amused at Mr. Lane's cynical remark as to the unseaworthiness of the craft which my Directors steer. I can only say the craft now sails upon an even keel before the wind of popular favour, and its course, so far as I know, is clear of all shoals, breakers, and quicksands. I judge from the tenacity with which the shareholders hold to their shares that they are also well satisfied with their craft. There is plenty of room for both gas and electricity, and the latter will advance to a front rank, despite the attacks and opposition of the votaries of the former.—Yours, &c., H. TOWNER, Secretary.

Eastbourne, July 15, 1893.

LEGAL INTELLIGENCE.

Blackie v. Electricity Supply Corporation (Limited).

The further hearing of this case was resumed on Friday last by Mr. Justic Cave and a special jury. Several additional witnesses were called for the defence to state that they were unable to detect any appreciable vibration in the neighbourhood of the plaintiff's premises or of the defendants' works.

Mr. MOULTON and Mr. BOUSFIELD addressed the jury, and the learned JUDGE, in summing up, said that when a person made use of his land in a way differing from others round about he must take care not to inflict injury or discomfort on others. In this case the defendants clearly were not doing what people all round were doing. The test was had the defendants done anything which had made the enjoyment of the plaintiff's house uncomfortable, or had they seriously interfered with the plaintiff's carrying on his business? If either had happened, then the plaintiff was entitled to a verdict. If neither had happened, then the defendants were entitled to a verdict. It was said that the defendants had communicated vibration to plaintiff's property. If they had done that so as to substantially interfere with his comfort or his business, then the plaintiff would be entitled to a verdict. The plaintiff had two strings to his bow—first, an alleged interference with his comfort; secondly, an interference with his business.

After a retirement of an hour and a-half, having in the interval sent a message to the Judge that they were unable to agree, the jury returned a verdict to the effect that they found there was vibration upon the plaintiff's premises, but that it was of so slight a character as not to materially interfere either with the ordinary enjoyment of his house or with the conduct of his business.

His LORDSHIP said this was a verdict for the defendants, for whom he gave judgment, certifying for a special jury.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Richmond (Surrey) Town Council invite tenders for the supply and laying of fire-calls within the borough. Specifications and forms of tender are to be obtained from Mr. F. B. Senior, the town clerk, to whom tenders must be delivered by 2 p.m. on Wednesday, the 2nd prox. Further particulars appear in our advertisement columns.

——— The Electric Lighting Committee of the Halifax Corporation are prepared to receive tenders for the supply of three boilers. Specifications and forms of tender are to be obtained from Mr. T. P. Wilmshurst, the borough electrical engineer, and tenders must reach Mr. Keighley Walton, the town clerk, by 10 a.m. on Friday, the 4th prox. Further particulars appear elsewhere.

——— The Cardiff Corporation require about 150 tons of cast-iron pipes and about 200 draw and junction boxes, tenders for which must be in by Wednesday next.

TENDERS RECEIVED.—The following were the tenders received by the Portsmouth Town Council for the supply and laying of the electric lighting mains :—

Messrs. Reid Bros.	£15,244
Messrs. W. T. Glover and Co.	15,221
W. T. Henley's Telegraph Works Company (Limited)	14,579
Messrs. Siemens Bros. and Co. (Limited)	13,407
India-Rubber, Gutta-Percha, and Telegraph Works Company (Limited)	12,712
Callender's Bitumen, Telegraph, &c., Company (Limited)	12,537
International Electric Subway Company (Limited)	12,043
British Insulated Wire Company (Limited)	11,673

As stated in *The Electrician* last week, the tender of the International Electric Subway Company was accepted, the total amount (inclusive of all accessories) being £13,539.

TENDERS ACCEPTED.—The tender of Messrs. Drake and Gorham has been accepted by the Richmond Main Sewerage Board for providing and fixing the necessary apparatus for lighting their works at Mortlake by electricity.

——— The Police Commissioners of Moffat have accepted the estimate of Messrs. Woodhouse and Rawson United (Limited), of Glasgow, for installing the electric light in the burgh, at a total cost of £4,000. The power will be derived from the falls at Skellywell, on the River Evan, nearly two miles from Moffat.

——— The tender of Mr. F. M. Newton, of Taunton, has been accepted for the lighting of the Dorset County Asylum. The installation consists of about 1,000 incandescent lamps. Taunton dynamos will be used, coupled direct to Willans high-speed engines.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price, and Goulty announce a sale on the 26th inst. of engines, boilers, shafting, steam-hammers, machine tools, and plant at the Canal-street Ironworks, Derby, the sale to commence at eleven o'clock for twelve o'clock prompt. Catalogues are ready, and can be obtained of the auctioneers, 49, Queen Victoria-street, London, E.C., or Albert-square, Manchester.

PLANT FOR SALE.—Mr. Thomas Oliver, of Totley, near Sheffield, has for sale an electric light plant, comprising a compound-wound Silvertown dynamo, a main switch and fuse-board, some cable and fittings, and a number of lamps, for further particulars of which see advertisement columns.

BANKRUPTCY.—Thomas Fletcher, electrician, of 188, Broadhurst-gardens, West Hampstead, has been adjudicated a bankrupt.——Proofs of debts against Frederick G. Robinson (separate estate), electrical engineer, of 97, Leopold-street, Kensington, Liverpool, must be in by August 2nd to Mr. A. Thraves, 15, Victoria-street, Liverpool.

APPOINTMENT.—Messrs. Urquhart and Small have been appointed electrical engineers for the borough of Richmond (Surrey).

——— Mr. G. F. Metzger, chief engineer of the Bath Electric Lighting and Engineering Company, has been appointed general manager in the place of Mr. Massingham, who has resigned that position.

MR. F. ESPIR.—We learn that Mr. Espir has been appointed sole agent in Great Britain and Ireland for the Budapest Incandescence Lamp Company.

CHANGES OF ADDRESS.—The registered offices of the Electric Construction Company (Limited) are now at Queen-street-chambers, Queen-street, Cheapside, E.C.——In consequence of the disastrous fire in St. Mary-axe, Messrs. Davis and Soper, the agents of the Johannesburg Lighting Company, have taken offices at 6, Great Winchester-street, E.C.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company have completed the laying of mains and are now supplying current in the following streets, which were lately added to their area of supply :—Cheyne-gardens, Cheyne-walk, Chelsea-embankment, St. Leonard's-terrace, Tedworth-square, Tite-street, Ralston-street, Durham-place, Oakley-street, King's-road. Large additions to the Company's plant and further extensions of mains are being made.

MR. E. LANSARD.—We have received printed particulars of a "New Electrical Combination Contact and Switch with Automatic Replacement," manufactured by Mr. Lansard, who is the inventor and patentee. Mr. Lansard claims that this combination dispenses with expensive switches and also with the inconvenience of getting to the switch. Any single door or call may be used or switched off without disturbing any other part of the installation, and the switch is automatically brought into its normal position by the closing of the door.

CROSSLEY'S "OTTO" GAS ENGINE.—We have received from Messrs. Crossley Bros. (Limited) an intimation that new sheets of price-lists, showing the reduced prices of their engines, can be obtained on application at Openshaw, Manchester, or at the numerous branches throughout the country.

FORTHCOMING BOOKS.—Messrs. Whittaker and Co. announce a "Manual of Telephony," by Mr. W. H. Preece and Mr. A. J. Stubbs, which will be ready early next month. The book will consist of about 500 pages. A large number of original illustrations have been prepared for the book.

"SCREWS AND SCREW MAKING."—We have received from the Britannia Company a copy of a new work under the above title, which will be found of considerable interest to those engaged in engineering pursuits. The work is well illustrated—of course, chiefly with illustrations of the tools and machines made by the Britannia Company—and it also contains a variety of tabulated and general information which will be found serviceable by many of our readers.

"ADRESSBUCH DER ELEKTROTECHNIK."—We have received from Herr A. Balck a list of German electrical firms arranged in towns, which forms a useful appendix to his "Adressbuch" published last year, and of which it is to make a third part.

HOLIDAY TRIPS.—We have received a copy of the summer number of the *Western Morning News* (price 2d.), containing illustrated descriptions of the watering-places in the West of England, with a very complete list of conveyances, which will be found of special interest to intending visitors to these popular resorts. This is a new journalistic departure in the West, and great credit is due to Mr. Ernest Croft for its production.

THE EDISON AND SWAN COMPANY.—The annual excursion of the *employés* took place on Saturday last, when about 600 went to Hastings, where an enjoyable day was spent. After a pleasant morning, about 400 sat down to dinner in the public hall, the company including the Manager of the works (Mr. Edward Gimingham), who occupied the chair, Messrs. P. H. Bell, C. M. Downie, Mancur, W. Young, A. W. Hill, A. Abercrombie, C. Faraday Proctor, A. H. Bate, Cooke, and others. In the evening about 100 of the female hands were regaled.

ABERDEEN.—Out of the applicants for the post of City Electrical Engineer four names—those of Messrs. John Christie (Glasgow), Alfred H. Gibbings (Hove), E. T. Ruthven Murray (Larne), and Fred. A. Nixon (London)—have been selected from which to make a final decision on August 7th.

BEDFORD.—The Bedford Electric Light Company (Limited) notify the Corporation that they intend applying to the Board of Trade for a Provisional Order authorising them to supply electricity within the Council's district.

BROMLEY.—The Local Board at their last meeting resolved to borrow £3,175 for the purchase of land in Station-road as a site for the electric lighting station.

CHATSWORTH.—This famous Derbyshire mansion is being fitted with the electric light under the supervision of Mr. B. Drake, who proposes to utilise the water-power already laid on for the supply of the fountains, from which source he estimates he can obtain 150 H.P. for the generation of the electric light. The installation, which will be one of the largest examples of the utilisation of water-power for country house lighting, is expected to be completed by the end of September.

CROYDON.—At the last meeting of the Town Council the report of the Electric Lighting Sub-Committee recommending that the Council carry out the lighting of the compulsory area in accordance with Mr. Preece's report, at an estimated cost of £25,000, was under consideration. After some discussion the Council voted, when

Digitized by Google

there appeared an equal number for and against the adoption of the report, and in the end it was referred back to the Committee for further consideration.

DUNDEE.—Electricity is being developed in Dundee as a motive-power as well as an illuminant, several tradesmen having had small motors fitted up for use in connection with their businesses.

GUILDFORD.—The Holloway Electricity Supply Company (Limited) have notified the Urban Sanitary Authority that they intend making application for a Provisional Order for empowering them to supply electricity at Guildford.

HAMMERSMITH.—At the last meeting of the Vestry the Electric Lighting Committee reported that they had appointed a sub-committee to go into the whole of the question of electric lighting generally, and to report thereon.

HUDDERSFIELD.—The parish church is being installed with the electric light.

LAMBETH.—The Vestry decided at a meeting last week to defer taking any action under their Provisional Order for six months.

LEEDS.—The desirability of acquiring new plant for the electric lighting installation of the Leeds Municipal Offices and Town Hall is under consideration, the existing machinery being now inadequate for maintaining the light at its proper standard. The probable outlay would be between £10,000 and £12,000.

SHEFFIELD.—At the last meeting of the City Council, on a motion for the approval of the minutes of the Highway and Sewerage Committee, Alderman Carter called attention to a resolution of the Committee dealing with the construction of transformer chambers by the local Electric Lighting Company, and charging a rental for many of them. He moved an amendment that the matter be referred back to the Committee for reconsideration, as he did not see why this Company should be placed on any different footing from the Gas Company. The Deputy Town Clerk having given his opinion that a charge for these chambers could not be legally enforced, the amendment was carried.

SHREWSBURY.—The Shrewsbury Electric Lighting Company (Limited) have notified the Town Council of their intention to apply for a Provisional Order empowering them to light the town by electricity. A resolution has been carried by the Council extending the period during which they would have the right to purchase the works from seven or fourteen years to twenty-one, but the final discussion of the question is adjourned.

WESTON-SUPER-MARE.—At the last meeting of the Town Commissioners it was resolved to request the Brush Electrical Engineering Company (Limited) to make an offer to the Board for the purchase of their Provisional Order for a term of years, and also to submit a tender for the erection of works for the supply of electricity, together with an approximate estimate of outlay necessary, supposing the Board were to undertake its own works.

WINCHESTER.—The Town Council of the City of Winchester have appointed Messrs. Morgan Williams and King, consulting engineers, to adjudicate in the matter of the award of the premium offered for the best scheme delivered to them for the electric lighting of the city.

WINDSOR.—At the last meeting of the Town Council the Town Clerk read some correspondence which had passed between the Board of Trade and the Windsor and Eton Electric Light Company (Limited), in which the Board requested the Company to forward reasons why their Provisional Order should not be revoked. The solicitor to the Company had replied that they had every hope before very long of being able to obtain the necessary further capital, and to extend their operations, and requested the Board to allow the question of revocation to stand over for the present. The Town Council eventually appointed a committee to seek an interview with the Electric Light Company officials with the object of ascertaining whether the Company would soon be able to comply with the Board of Trade requirements.

WOLVERHAMPTON.—The Local Government Board will hold an inquiry on Wednesday next at the Town Hall, Wolverhampton, respecting the application of the Town Council for sanction to borrow, amongst other amounts, £1,927 for electric lighting purposes.

The Candle-Power of Arc Lamps.—It was recently stated that independent tests of 23 arc lamps in the streets of Buffalo (N.Y.) had revealed the fact that the so-called 2,000 c.p. lamps gave, on an average, only 807½ candles. The electric light company has now replied to this by publishing the results of tests made on its behalf by a committee composed of two professors and a doctor. This committee tested over 100 lamps, and the results obtained were all well above 2,000 candles; some of them were nearer 3,000 candles.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

June 13, 1893.

11,609. J. F. MCELROY. London. Improvements in electric switches.*

11,610. C. J. YARNOLD. London. Improvements in apparatus employed in the evolution and collection of hydrogen and oxygen gases by electrolysis

11,622. R. H. SANDERS and C. T. THOMPSON. London. Process of magnetic separation and apparatus adapted to the conduct of such process.*

11,649. Sir C. S. FORBES (Bart.). London. Improvements in apparatus for facilitating telephonic intercommunication.

June 14, 1893.

11,680. F. SAUER and C. AEUTZCHEL. Manchester. Improvements in electric alarm apparatus for doors, windows and the like.

11,716. C. PARKES. The "preventum" crank and wire and electric pull-out bell pull.

11,717. THE SAFETY TREAD SYNDICATE (LIMITED), JOSEPH MASON and JONATHAN MASON. London. Improvements in coal plates, covers for cellars, electric light boxes and like purposes.

11,728. E. F. MOY. London. Improvements in switches for electric currents.

11,729. P. REINER. London. Improvements in coin freed machines for administering electric currents.*

11,749. A. B. WOAKES. London. Improvements in heating liquids by electricity.

June 15, 1893.

11,759. C. TURNBULL, JUNIOR. Newcastle-on-Tyne. Improvements in or relating to electric bells.

11,801. C. N. RUSSELL. London. Improved means and appliances connected with securing electric light fittings.

11,819. E. H. ALLEN. London. Improvements in electric railway trolleys. (Date applied for under Patents Act, 1883, Sec. 103, November 16, 1892, being date of application in United States.)*

June 16, 1893.

11,842. E. PAYNE. Cuckfield. Improvements connected with the insulation of electrical conductors.

11,890. P. RABBIDGE. London. Improvements relating to telephones.

June 17, 1893.

11,921. W. H. JOHNSON. Southampton. Improvements in and relating to suspensory apparatus designed more especially for electric and other hanging lamps, but adapted for suspending and regulating the height of suspension of other articles.

11,973. SIEMENS BROS. AND CO. (LIMITED) and E. F. A. OBACH. London. Improvements in apparatus for electrolysis of water.

11,977. J. O. COWPER. Coles. Improvements in electrical search and signalling apparatus.

11,983. D. G. FITZGERALD. London. Contact plates or electrodes for forming and charging, or for alternately charging and discharging plates or elements to be used in voltaic batteries.

June 19, 1893.

12,006. J. STRONG. London. Strongs' arc-lamp.

12,011. R. BROWN. Preston. Electric low-water alarm for steam boilers.

12,032. EASTON AND ANDERSON (LIMITED), and E. W. ANDERSON. Improvements in electric travelling cranes or hoists.

June 20, 1893.

12,070. C. RICHARDSON and E. G. HERBERT. Manchester. Improvements in switches for controlling electric currents.

12,139. M. HUIIN and M. LE BLANC. London. Improvements in electric machines and transformers.

12,141. E. TYER. London. Improvements in electrical time switches for signalling.

12,142. E. TYER. London. A safety switch for electrical lock and block apparatus on railways.

12,143. E. TYER. London. Electrical apparatus worked by passage of a railway train or vehicle.

12,153 A. G. WATERHOUSE. London. Improvements relating to methods of measuring, controlling, and regulating electric currents, and to apparatus therefor.

June 21, 1893.

12,191. W. H. INGALL. Birmingham. An improved globe or shade holder for electric gas or other lamps.

12,196. Sir C. S. FORBES, Bart. Improvements in the arrangement of telephone circuits, and switching devices therefor.

12,233. J. GOTT. London. Improvements in controlling, adjusting, and mounting movable coils in telegraph recording instruments. (Charles Cuttriss, United States.)

12,242. J. E. SENECHAL. London. An improved electric lighting device.

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-second half-yearly General Meeting of this Company was held on Thursday, July 13th, at Winchester House, Old Broad-street, London, E.C., under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting and the minutes of the last meeting, which were confirmed,

The CHAIRMAN said: Gentlemen—You have had the report in your hands for some time, and I presume that you will, as usual, take it as read. Before I ask you to approve the report I will, as usual, go into some of the details, so that you may have the fullest information that it is in our power to give as to the working of the Company during the last six months. The gross revenue for the half-year under review amounted to £372,852 as against £382,207, or a decrease of £9,355. Analysing the receipts from various sources, we find an increase of about £3,000 in the message receipts. There is a reduction in the traffic with several places, esp ecially South America and Portugal, but this is more than recouped by the increase in other directions, notably South Africa, Egypt, Turkey, India, and beyond. The reduction in the gross revenue is due to our having received £17,700 from our investment in the shares of the Eastern and South African Telegraph Company as against £29,500 in the corresponding period, or a decrease of £11.800. I may explain to you, again, regarding this investment in the Eastern and South African Company, that

Digitized by Google

that Company is practically an arm of this Company, but for many reasons which I need not explain to-day, on account of our concessions and for other reasons, it is necessary for us to work the two Companies separately. The large bulk of the shares, however, is held by this Company. That Company, instead of paying 10 per cent. this last year, paid only 8 per cent., but there were reasons for making the reduction. There was the sort of shadow that had overcome the African traffic, and altogether the reasons were such that the Eastern and South African Company thought it was more prudent to pay 8 per cent. instead of 10 per cent. Still, notwithstanding that reduction, I think I shall be able to show you, before I finish my remarks, that this Company stands to-day in probably a better position than it has ever before been my pleasure to report to you.

That, however, is a statement a little in anticipation. You will get the facts more as I go on with my remarks. The total ordinary expenses for the half-year ended March 31, 1893, amounted to £102,499 as against £105,820, or a decrease of £3,321. The details are as following:—General expenses in London £9,369 as against £9,589, or a decrease of £220. Working expenses at stations £79,926 as against £78,695, or an increase of £1,231. Several of the items under this head show substantial decreases. The principal increase is in the salaries and wages of our staff at stations, there being an increase of thirty clerks compared with the corresponding period of last year. There is also to be taken into account the operation of the scheme adopted some years ago to provide a regular scale of promotions for the younger men as they qualify themselves by accuracy and speed in working, as well as by general good conduct and intelligent progress. You can quite understand that a staff cannot remain in the same position from year to year. As our business progresses we not only have to add many additional clerks but the younger clerks become older, and have to be considered in connection with the question of promotion. You cannot effect promotion generally without putting your hand into your pocket; but still, all these things are in keeping with the general growth of the Company, and as the Company improves generally, which it is doing, the clerks are naturally entitled to some consideration. The following accounts show reductions: Special repairs to buildings at stations, £1,974; and negotiations with foreign Governments, £1,375. Other telegraph companies hiring our ships have been charged a proportion of the depreciation for the period the ships were on their work. We have, therefore, for the half-year under review, a charge of only £2,245 against revenue account for maintenance ships' fund, against £4,000 in the corresponding period of last year. Our ships have been employed in doing a great deal of work outside our own system, and that reduces the general costs under this heading. The expenses attending repairs and renewals of cables amounted to £32,533 as against £53,515, or a decrease of £20,982. It will be seen from abstract C at page 6 that we have received during the half-year over £26,000 for the hire of our ships for cable-repairing purposes. That tells in two ways. The earnings of the ships bring money into our exchequer; and, moreover, if these ships had been employed in repairing our own cables it would represent a double loss, as you can quite understand. There is no position which the ships occupy so satisfactory to the Company as when they are doing nothing in regard to our own cables, but we have found out lately that while they are doing nothing for us we can obtain employment for them in doing work for other people. We have got paid in that way, and we also save the expenses of maintenance ships in a very handsome manner. In these times £26,000 is a large sum of money, and probably there are many shipowners now who would look on that amount as a very nice return on a larger number of ships than we have at our disposal. I may tell you that we keep our fleet fully manned and in a thorough state of efficiency, ready for repairs at short notice. Sometimes they are fully occupied on our own work, but when we can spare them for repairs to the cables of other companies it tends, as I have already said, materially to keep down the cost of our own repairs, as is amply demonstrated this half-year. After providing the usual amounts for interest on debentures, debenture stock, and Preference shares, we are able to propose the usual final dividend of 1¼ per cent., and a bonus of 1½ per cent., making with the interim dividends already paid, a total distribution of 6½ per cent. for the year ended March 31, 1893, and to carry the sum of £88,000 to the reserve fund, against £68,000 in the corresponding period of last year.

I think that justifies the remark that I made earlier in regard to our position to-day. Last half-year when I was addressing you I said that I believed I was putting before you the best account we had ever presented you with since the beginning of the Company, but I think we have improved materially upon last half-year. I only regret that this improvement, more or less, arises out of a great many of the disasters that we have been hearing about. We find that our Company and telegraph companies generally, and submarine telegraphs in particular, are so much used now for commercial purposes in every part of the world that when good times exist we get a very fair share of the traffic, and that when bad times come we are employed in order that those bad times may be brought to an end as quickly as possible. We have seen lately certain banks going down like so many ninepins, whose businesses have to be reconstructed. All these circumstances tell to the benefit of the submarine telegraph system, and give us now a more satisfactory view of it as being a stable investment than at any period probably of our history. We are very young yet, scarcely 25 years old, but still we are now holding a position among the companies of this great City of London second to none. During all these hard times the value of our shares has been maintained on the Stock Exchange, and we have deserved to maintain the value of this property, because we have given very strong evidence of its satisfactory position and its increasing prosperity. Every year and every half-year we are learning something. Like electricity itself, which may be said to be in its infancy, we have attained very strong manhood in a very limited number of years. When the Company arrives at a good age I hope its position will be still better than it is to-day. It is probably at the head of all institutions of the kind, and all of us who are connected with it ought to be proud of the position that it occupies. A circumstance occurred the other day in connection with which we took a course which I am sure the shareholders will approve. When war has occurred in previous years we have always tried to help those who could not help themselves; we have always endeavoured to ameliorate the condition of wounded soldiers and sailors, and we have received letters of gratitude from time to time from the parents and relatives of these people which are very touching indeed. When the "Victoria" disaster occurred the other day we found that there were many in this country who were deeply anxious as to the fate of their relatives or friends on board, and who desired to know who had been saved from that terrible disaster. I therefore wrote at once to Admiral Hoskins, saying that whatever he or the Admiral at Malta thought ought to pass over our lines free for these poor people—and for officers also—the Company would be glad to accept (hear, hear). As you are aware, the Company was publicly thanked in the House of Lords by Earl Spencer, and I am quite sure that you will to-day endorse our action, which brought comfort to some homes, though, unhappily, sorrow to others.

I will now continue my remarks regarding the financial position of the Company. We have applied a further sum of £54,077 from reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable and other capital expenditure, so that our capital expenditure, with the exception of some small additions to our land and buildings, remains at the same figure as last year. The total amount applied out of the reserve fund from time to time now reaches the substantial sum of £1,256,822. That, gentlemen, amounts to this, that we have practically duplicated, and in some cases triplicated, our system without increasing our capital. You can all understand the benefit of keeping down the capital. By doing so we secure for you in every way something like a permanent income. We cannot stand still as a Company, as I shall show you as I go on. I think at the last meeting I mentioned to you that we had entered into an arrangement with the Government for laying a cable from Zanzibar to Seychelles and Mauritius. After considerable delays the negotiations were concluded, and the documents are all signed; and I believe that before the end of the year we shall have completed that important additional link in our very important chain of submarine cables. I may state that in regard to this concession which I have just mentioned, several other parties applied for it, but none of them were in the position that we are in. We have so built ourselves in around there, with our system extending all over the world, that we occupy such a position that no one can compete effectually with us. The time we devoted to this work was very considerable, and the consequence was that, after due consideration, the Government entered into this arrangement with us. They did so with their usual keenness, and harder men at driving a bargain I have never come in contact with. Still, when a bargain is made they stick to it. The line is largely strategical as well as commercial. As I said at the time, it is absolutely necessary to lay a line to Mauritius to connect her by our system with India and other parts of the world. Competition is active there as elsewhere, between cane sugar and beet sugar, but cane sugar will always beat the other if there are only proper facilities given to it. I hope, therefore, that this new line will greatly benefit Mauritius, and that it will also contribute in maintaining that *esprit de corps* which makes Englishmen at the head of the commercial world.

We had another interesting "battle," as I may call it. We had practically secured a concession from Portugal to lay a cable for connecting the Islands of the Azores with Lisbon. We went into that matter for the reason that one of the conditions was that the privileges we had enjoyed at Lisbon would be extended for another ten years if this cable were laid. In doing this work we are associated with other companies, but we obtained a very great advantage also for the Eastern Company. The contract has been signed by the Minister subject to the approval of the Cortes, which there was every reason to believe would confirm it, when a French company came in with the support of the French Government on so-called political grounds, which, in our opinion, the enterprise did not involve. Let me tell you that the French Government do not hesitate to say and do straight things in support of their people, whereas our Government does not do so, but leaves us to fight our own battles. The result in this case was that for the moment the French succeeded in taking away the concession from us. But the French company having failed to carry out the work within the term of one year fixed by the concession, we were invited last May by the Portuguese Government to resume the negotiations which finally culminated in the contract being definitely granted and signed on June 17th.

I have given you a great deal of information to-day, but I have not done yet, although I have finished the financial part of my information. I have now, however, to refer to the death of our late Managing Director. I believe there are many shareholders present who during the last quarter of a century have seen Sir James Anderson occupying his place here from six months to six months. He was a trusted and valued colleague, and I am sure I can say, working with him as I did for nearly 25 years, that he was always ready and always willing to promote the welfare of this Company, which it was his ambition to see take the very high position it has attained to. We, therefore, very greatly regret the death of our valued and honoured colleague, and I am quite sure that you will join in this expression. I have now referred to almost everything excepting the last point that I have to bring before you, namely, the appointment of my son, Mr. J. Denison Pender, to the position which Sir James Anderson occupied. My son is young, but he has been trained for this work, to which he has served a good long apprenticeship. Very few men know more about boats or about the work generally on which he is now engaged. I may say that the suggestion that my son should take this position did not come from me so much as from other members of the Board. They thought he was a competent man, and the proper man for the place. In speaking to my son on this matter I said to him: "You know this work. I could not put my finger on a man who would do it better than you can, but you

Digitized by Google

must make up your mind in entering upon it that you must do so with an earnestness of purpose and continue the work which your father and older men connected with it have carried on. You must take up the work with vigour and energy, and success will only be attained by you by devotion to the work you are asked to undertake." I may tell you, gentlemen, that this appointment was not made in order to place my son in this position, because he is perfectly independent of any such position; but he loves work, he knows the work that has to be done, he is proud of the position which the Company holds, and he has accepted the appointment with the determination to carry out the work as it has always been carried out—with vigour, energy, and economy. I now beg to move the following resolution:—

"*That the printed report and accounts of the Directors to March* 31, 1893, *submitted to this meeting, be and the same are hereby received and adopted; that a dividend on the Preference shares of the Company to June* 30, 1893, *at the rate of* 6 *per cent. per annum, be paid, less income-tax; and that in accordance with the Directors' recommendation, a dividend be and is now declared of* 2*s.* 6*d. per share, with a bonus of* 3*s. per share, both free of income tax, on the Ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of* 6½ *per cent. on those shares for the year ended March* 31, 1893."

The VICE-CHAIRMAN (The Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: If any gentleman desires to put any questions to me I shall only be too ready to answer them to the best of my ability.

Mr. W. GOODSALL: I read in one of the papers this season a report stating that Sir John Pender was enjoying a well-earned holiday in the Levant with a party of noble friends. I should like to ask whether the vessel, the "Mirror," was Sir John's own yacht, as stated, or whether it was one of the vessels of the Company? If the latter, I should like to know what the cost of the little trip was. I understand that Sir John Pender's son has been appointed Managing Director of the Company; and he is also, I believe, a Director of the Telegraph Construction and Maintenance Company. (No, no.) He is not? (No.) Then I will not say anything more on that point. As long as you say that I do not wish to say anything further.

Mr. BAINES: Before you reply to Mr. Goodsall I should like to make one or two remarks regarding the very stationary character of the dividend. I listened with great pleasure to what the Chairman said, and he congratulated us on our position at the present time. I am sorry to disturb the harmony of his remarks, but it seems to me that as we are doing so extremely well, the interests of the shareholders might be a little better cared for. This Company has a very ample capital and is conferring great benefit on the commercial world as well as on the community generally: and I think that a Company like this ought to pay a better dividend, especially considering the risky character of our property. Banks pay 8 per cent. or 10 per cent., but we do not seem to be able to get beyond 6½ per cent. At the inception of our Company the prospect of very large dividends was held out, but certain circumstances arose with which the shareholders are familiar, and we were disappointed by the code system. Still, I think it is the duty of the Directors to see if they cannot make up to us for that. The shareholders will notice also that every half-year large sums are carried to the reserve fund; in this past half-year alone, £88,000. No one can appreciate more than I do the value of a reserve fund. It is a very valuable asset, and strengthens our position in the share market, and enables us also to carry out projects which we could not otherwise do. But there is a limit to a reserve fund, I should say, and I think that some portion of this amount which is carried to reserve fund might be distributed among the shareholders, especially when we come to consider that the duplication of our cables, and not only that, but the laying of fresh cables, have been provided in a great measure out of revenue. I may be wrong, and I do not profess to be an adept in accounts, but it seems to me that when these large sums that have been earned by our original capital are diverted to these purposes some part of it belongs to us, and I think that the Directors should consider the propriety of giving to the shareholders a part of it *pro rata* to their holdings. This may be worthy of their attention. I think that the accounts want thoroughly overhauling, because I believe that economies might be effected if they were kept thoroughly well in hand. I have been a shareholder for many years, and some years ago I mentioned the circumstance of the electrician's retaining fee, which I believe was at that time about £150 every half-year, or £300 a year. The Directors looked into the matter, and found that they could cut this item down considerably, and they did so, and it now appears as £75. That was a step in the right direction. The gentleman behind me has referred to the appointment of Mr. Denison Pender. I have nothing much to say on that point, although I was going to ask if his qualifications fitted him for such a very important office. The Chairman says that they do, and under those circumstances I can say nothing further about it. With respect to these trips which Sir John Pender tells us every now and then he takes, he says that the different *employés* like to be called upon, and that the trips afford an opportunity of seeing the condition of our property. I have had some information conveyed to me, however, and I wish to ask whether it is the case that the "Mirror" goes into Marseilles or Malta, and is dismantled and then fitted up in a luxurious style, with an installation of electricity. It then goes into some port in the Mediterranean, where it quite astonishes people. That is what I hear, and I have no doubt it does do so. I do not object to these trips, but I think that more attention might be given to the interests of the shareholders.

Mr. JOHN NEWTON: I should like to say a few words with respect to the question of dividend and the position of the Company. I claim that this is not a risky property. The experience of 20 years which we have had proves that it is a very substantial and safe property, and as certain a one as you can put your money into. The market confirms that for no class of security stands so well as telegraph property at the present time. As regards the dividend, the gentleman who has just spoken on that matter has been a shareholder with me for more than 20 years. In former years we used strongly to criticise the Directors. I am very glad to see him continue that *rôle*, because it will not do the Directors harm or the Company either; but I take a different view. I am perfectly satisfied that this Company is doing as well as it can for its shareholders. My experience of former days was that we were not satisfied with 6½ per cent., because we had been promised 15 per cent. and 20 per cent. in the prospectus; but times change. There is, however, a point which all shareholders in telegraph property must not forget, and it is one that has troubled me much, namely, that as soon as you begin to advance your dividend beyond 6½ per cent. and go to 7 per cent., you will have the Conference after you, and have to take a reduced dividend. It is much better to spend your revenue in consolidating your property and increasing its strength, and commanding influence, than getting it in an increase of dividend. You get the benefit by the higher market value of your property when you wish to sell, or your children will get the benefit. If you doubt that try and buy 1,000 shares in the Eastern Telegraph Company at the price they are now quoted at, and you will find that you will have to pay much more. The reserve fund investments are as decided a testimony as you can have of the capacity of this Board. Look at the thousands and millions, you may say, that have been lost; but you have had money invested by this Company which is still intact, notwithstanding the disasters that have taken place. I say that there is no Board more entitled to the confidence of their shareholders than the Board of this Company. It is in the knowledge of that fact that I have taken the part which I have taken in recent years. I do not think that anyone who has put money into this Company has failed to make a profit, or he stands to make a profit. As regards the question that has been raised concerning the Chairman's trips, I must say that in my opinion it is perfectly right that someone should go and represent the Eastern Telegraph Company in the world beyond England. Whom could you select if you did not like the Chairman to go? (A voice: "You.") The Chairman is the proper man to go. I should be very pleased to go, but I should not represent the Company if I did. Someone, however, ought to go. Put the matter on a lower ground. What man would not do such a thing as this by way of advertisement if he possibly could? Thousands of pounds are spent in advertising in order to get at the position to which our Company has attained to-day. It is therefore simply ridiculous to grumble about the trips of the Chairman, because if he did not make them someone must, and no one could make them so well. With reference to the appointment of Sir John Pender's son, I know that someone has said that it is nepotism, but in great companies like this you must have young men who are capable. It is all very well having men who are advanced in years, but you have got enough of them on the Board now; and Mr. Denison Pender has been trained to the work, no doubt. If he has not, he ought to have been. If I had had a father in his position, I know that I should have known something about the work (laughter). With a company doing such work as this, and standing in such a position as it does, there ought not to be anything in the nature of criticism unless there is reason for it.

Mr. BAINES: I should like to add a few words to what I said before. I forgot to say then that I desire to tender an expression of my regret at the death of Sir James Anderson. I may say with regard to what the last speaker has said about the dividend and the Conference coming down on us if you increase it, you can issue additional shares *pro rata*, so that the shareholders might receive some benefit.

The CHAIRMAN: There is nothing I enjoy so much as a little criticism; but there is nothing that astonishes me so much as that the criticism should come from the quarters where it has emanated from to-day. I am not going to say a disrespectful word of any gentleman; but I will say this—that the larger interests involved in the Company have all been complimentary to us, and not in any way adverse. When I go back to the time more particularly that our friend referred to, when he first became a strong critic of the Board, and when we see the contrast between those days and these, I think he might have had the nobility of character to say that he was disappointed in his early days, but that we had made this the great concern we thought we should make it; and that he was wrong then, and would now come to help us. Instead of that, he comes here to try and depreciate what you all acknowledge to be a great success—a marked success of the times. You can therefore well understand that I look upon his criticism as being rather complimentary than otherwise. Two gentlemen have referred to the trips which I occasionally take. I wish I could take them oftener. My time, however, is too valuable to enable me to go, but I think if I were to come to the Company and say that you ought to pay me a considerable sum for every trip I take, it would be to your interest to make the payment. I charge the Company nothing for the time I expend in their interest beyond the regular remuneration which I receive as a Director. I go on these trips from time to time, and I do great and good work for the benefit of this Company. This very contract for the Azores cable which I have brought before you to-day was absolutely, I believe, the result of my visit to Portugal. They paid me there the highest compliment they could by conferring upon me the highest honour which the Portuguese Government can give to a private individual; and is that not a compliment to this Company, and is it not to the benefit of the shareholders of the Company? Do not suppose that I go out on these trips merely for pleasure. I never lose sight of the interest of this Company. I have been to Turkey, and you know what good I did there for you; and I have been to Portugal and to Athens, and those visits were also beneficial to you. We have had great difficulties with France, but still, when I went there they presented me, as your Chairman, with the Order of the Legion of Honour, which is an honour they rarely confer upon anyone out of their own country. I mention these things not in an egotistical manner, but in order to let you see that the countries of the world

Digitized by Google

appreciate the work we are doing. I say it is a very small thing for any member of this great Company to come here and try and depreciate those who are doing so much both to maintain and to exalt the position of the Company. The object of every act of mine in connection with this Company is intended for the benefit of its shareholders.

Mr. BAINES: I said distinctly that I did not object to your trips.

The CHAIRMAN: I am not referring to any one in particular, but to those who try to lower the dignity and standing of this Company. Mr. Newton has for many years watched the progress of this Company. I have always acknowledged his criticism as being fair and just. He knows pretty well what we are doing, and is shrewd enough to tell us when we are not going in the right direction. He has made remarks to-day which I ask the shareholders to remember. If the management of this Company had not been in the hands of thoughtful, prudent, and cautious men, you would not be occupying the position you do to-day. It is with companies as with men. If you want to be strong in social life, in political life, or in any position in life where wealth is more or less respected as a great power, you must fortify yourself in that direction. I say that if we had not laid down the policy and carried it out strictly of having a large reserve fund, you would not be in your present position. We have done more than that, for we have practically duplicated, and in some cases triplicated, the system without materially increasing the capital. What more do you want than that? I think I have now said enough to satisfy you that if we saw that it was prudent, and that the time had come when we could increase your dividend, the Directors would be only too glad to do it; but, still, we are increasing the value of your stocks, as you must admit, and you cannot have your cake and eat it too. Although we are not giving an extra 1 per cent., we are adding to the value of your property considerably, and that is the way you ought to look at the matter. When the time comes, and we have completed our work—we have still two big jobs to do—and when money comes in more freely than we can see our way to invest it, you may depend upon it that the shareholders will have our first consideration.

Mr. BAINES: That is what I wanted to know.

The CHAIRMAN: I think I have now said all that I had to say, and I will therefore submit the resolution. Those who are in favour of it will please hold up their hands; on the contrary; it is carried unanimously. That finishes the business of the meeting. If I have spoken a little warmly ("no, no") you may depend upon it that I have spoken in your interests. I am proud of this position, and I do get a little warm sometimes when I find that it is in any way assailed. I do not mean to say that you (to Mr. Baines) assailed us, or went very far out of the way, but still you did a little (laughter).

Mr. BAINES: I did not catch what you said, but we have had tussles before. You have had struggles with me before, and so have I with you. We both hit from the shoulder, but we are none the worse friends for that, I hope. I propose a vote of thanks to the Chairman, Directors, and staff, and I think we may congratulate ourselves on having such a Chairman and such Directors. At the same time I think a little criticism does good, and I do not think that Sir John Pender need feel very angry with me.

Mr. NEWTON: I will second that. I wish also to make good an omission in my former remarks, as Mr. Baines did, by regretting the great loss which the Company has sustained by the death of Sir James Anderson. I wish to join in the expression of sympathy which you have given utterance to in regard to that matter. I hope that Mr. Denison Pender will follow in Sir James Anderson's footsteps, and be as capable and successful in our affairs as our late Managing Director was.

The resolution was carried unanimously.

The CHAIRMAN: I beg to thank you very warmly for this vote, and I thank Mr. Baines also for the pleasant way in which he has brought this meeting to an end. There is nothing I like so much, I say it again, as to be able to hit out when I am hit at; but you may depend upon this, that these little episodes in our business show pretty well that there is good back in it. When I see so many gentlemen here who sympathise with, and approve of, the remarks I have made I do not regret what has happened. It has always been the desire of this Board to be in constant and friendly touch with our shareholders, and to have nothing in the background. We put everything before you regarding our affairs. If we do anything wrong we expect to be pulled up; but if we do everything that is right, and bring matters to a successful termination, we expect to be a little complimented by you.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The following is the report of the Directors, to be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, London, on Friday next, the 28th inst., at 2 p.m.

The total receipts from January 1 to June 30, 1893, including the balance of £737. 3s. 9d. brought forward from the last account, amounted to £148,185. 14s. 11d. This sum, however, is subject to revision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal in Paris, and will not be heard until after the vacation. The traffic receipts show an increase of £367, as compared with the corresponding period of last year.

The total expenses of the half-year, including the repair of cables, &c., as shown by the revenue account, amounted to £60,182. 13s. 2d., being an increase of £813. 11s. 4d. upon the corresponding period of 1892.

One quarterly interim dividend of 12s. 6d. per cent. on the Ordinary stock and of £1. 5s. per cent. on the Preferred stock, was paid on May 1, 1893, absorbing £43,750, and a second quarterly dividend at the same rates will be paid on August 1, 1893, leaving a balance of £503. 1s. 9d. to be carried forward to the next account.

The Company's repairing ss. "Minia" has been engaged during the past half-year in the following repairs, viz.:—Heart's Content and Placentia (Island Cove) cable, Placentia and Sydney (Southern) cable, St. Pierre and Duxbury cable, Brest and St. Pierre (1869) cable. Three breaks have occurred in the last-mentioned cable in deep water, one of which was repaired on June 10th, and the "Minia" is now employed in the repair of the other. The Valentia and Heart's Content cable, laid in 1874, was broken on July 9th 575 miles from Heart's Content; the Telegraph Construction and Maintenance Company's ss. "Calabria" has been chartered for the repair. The Company's other cables and land lines are in good working order and condition.

The Directors report with extreme regret the death of their late esteemed colleague, Sir James Anderson, which occurred on May 7th last, and at the same time desire to record and acknowledge the valuable services he rendered to the Company, not only at the time the Atlantic cables of 1865 and 1866 were laid, but during the many years he occupied a seat at this Board.

Direct United States Cable Company (Limited).

The following is the report of the Directors for the six months ended June 30th, to be presented at the thirty-second ordinary general meeting to be held at Room 174, Winchester House, Old Broad-street, on Friday next, the 28th inst., at 1 p.m.:—

The half-year's revenue, for the half-year ended June 30th, after deducting out-payments, amounted to £40,836. 17s. 4d., as compared with £39,014. 14s. 1d. for the corresponding period of 1892, being a difference of £1,822. 3s. 3d. in favour of the half-year under review. The working and other expenses for the same period, including income-tax, amounted to £18,898. 5s. 7d., leaving a balance of £21,938. 11s. 9d. as the net profit of the half-year, making with £3,129. 0s. 7d. brought forward from the previous half-year a total of £25,067. 12s. 4d. For the corresponding period 1892, the working expenses and other payments amounted to £19,013. 13s. 3d. Three quarterly interim dividends of 3s. 6d. each per share, amounting to £31,872. 15s., have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with three interim dividends, 3½ per cent. for the year, being a total distribution of £42,497. After transferring £3.000 to the reserve fund, which now stands at £267,415. 12s. 7d., the balance of £819. 2s. 9d. on the revenue account is proposed to be carried forward.

The new permanent structures at Ballinskelligs, consisting of a new station building and a house for the superintendent, are now completed and occupied. Two blocks of semi-detached cottages are needed at the station to replace the dilapidated wooden houses at present occupied by the married staff, and will be provided at an estimated cost of about £2,700. A new station for the acceptance and delivery of telegrams has been opened at 142A, Winchester House, Old Broad-street, E.C.

Pursuant to the provisions of the Articles of Association, two of the Directors, viz., Charles Meara, Esq., and E. M. Underdown, Esq., QC., retire by rotation, and being eligible offer themselves for re-election. Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

Globe Telegraph and Trust Company (Limited).

The following is the report of the Directors of this Company, to be presented to the twentieth ordinary general meeting, to be held on the 27th inst., at Winchester House, E.C., at one o'clock.

The net revenue of the Company for the year, after deduction of expenses, amounts to £188,931. 10s. 8d., and makes, with the balance £938. 4s. 1d. brought forward, a total of £189,869. 14s. 9d. From this amount there has been distributed the sum of £126.300. 16s. 8d. in interim dividends, leaving an available balance of £63,568. 18s. 1d.

The Directors recommend the payment of a final dividend for the year of 3s. per share on the Preference shares, and of 4s. per share on the Ordinary shares, making, with the previous distributions, a total dividend for the year of 6 per cent., less income-tax, upon the Preference, and 4 per cent. net (against 4⅞ per cent. for the preceding year) upon the Ordinary shares, and carrying forward a balance of £1,304. 17s. 9d.

The Directors report with much regret the death on May 7th last of Sir James Anderson, their valued and much esteemed colleague, who had been a Director of this Company from the date of its incorporation. The Hon. W. St. John F. Brodrick, M.P., a Director of the Brazilian Submarine Telegraph Company (Limited) has been elected to fill the vacancy.

Mr. Sidney Collett has been appointed secretary in place of the late Mr. William Payton, whose decease was announced in the last report. Since the last meeting a Staff Endowment Assurance Scheme has been carried into effect, the Company's contribution being about £100 per annum. In conformity with the Articles of Association, Sir Henry Daniel Gooch, Bart., and James Pender, Esq., two of the Directors, retire, and being eligible offer themselves for re-election. The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths, and Co.), and Mr. William Griffith, B.A., barrister-at-law, also retire; and Messrs. Deloitte, Dever, Griffiths, and Co., and Mr. Griffith offer themselves for election.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's Five per Cent. Debentures (1884 issue), due for payment 31st inst., will be paid on and after that date at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, London, E.C. The coupons should be left at the bank three days for examination.

Electric Construction Company (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel yesterday (Thursday) for the purpose of confirming as special resolutions the resolutions passed at an extraordinary general meeting held on July 5th (which were given in *The Electrician* of June 30th, page 248). Sir Daniel Cooper presided.

Mr. JAMES GRAY (the Secretary) read the notice calling the meeting and the above resolutions.

The CHAIRMAN said: Gentlemen—This meeting has been convened to comply with the Companies Acts and the Articles of Association of the Corporation to confirm, or otherwise, the resolutions passed at our general meeting on the 5th of this month. You will all have received a report of the proceedings at that meeting, and you will have observed that the resolutions proposed at that meeting in favour of a reconstruction of the Corporation were carried unanimously. You have also been informed that meetings of the holders of the First and Second Mortgage Debentures have been held, and that the scheme of reconstruction has been adopted by them, and if you confirm to-day, as I hope you will, the resolutions which I now propose, then the new Company will be registered to-day, and will take over the business of the Electric Construction Corporation and all its liabilities and assets as from the 1st of this month, and although there may be still several formal steps to be taken for the purpose of completing the matter, yet, practically speaking, the reconstruction of the Corporation will be effected by your confirming the resolutions to-day. I may tell you that the support we have received from the shareholders in favour of the resolutions now before you is even larger than the very gratifying support we had at the last meeting. It is not necessary for me to detain you any longer now. Before concluding, I may tell you that in accordance with the Companies Acts we shall have to hold a general meeting of the new Company within four months, so that we shall have an opportunity at an early date of meeting you again, and giving you further information in regard to the position of the new Company. I have, however, to add that after the special resolutions have been confirmed a further resolution will have to be proposed by the Chairman and seconded by the Right Hon. David Plunket, that Mr. Philip Edward Beachcroft and Mr. Emile Garcke be appointed joint liquidators of the Electric Construction Corporation, and that they be instructed to give effect to the special resolutions for winding up the Corporation with a view to its reconstruction.

Mr. BARCLAY having seconded the resolutions,

The CHAIRMAN invited discussion, and there being no questions asked he put the first resolution to the meeting, and it was at once carried unanimously. He then, with the permission of the meeting, put all the resolutions, from 2 to 8 inclusive, *en bloc*, and they were also carried unanimously.

The CHAIRMAN then moved that Mr. Philip Edward Beachcroft and Mr. Emile Garcke be appointed joint liquidators of the Electric Construction Corporation (Limited), which was seconded by the Right Hon. D. PLUNKET, and carried.

A vote of thanks to the Chairman having been moved and seconded,

The CHAIRMAN, in reply, said: Gentlemen, I have to thank you for your vote. I have not had much anxiety to-day. I can assure you that myself and the whole Board of the Directors feel very greatly indeed the kind support that you have given us under adverse circumstances. We trust that we may rely upon its continuance. We feel that we are very much indebted to you, and we thank you very cordially that you have given us such very great support.

The proceedings then terminated.

National Telephone Company (Limited).

The thirteenth annual ordinary general meeting of this Company was held at the City Terminus Hotel on Tuesday last, the President (Mr. James Staats Forbes) in the chair.

The SECRETARY (Mr. A. Anns) read the notice convening the meeting, and the Directors report and statement of accounts were taken as read.

The CHAIRMAN said that there were on the register 6,721 shareholders and 1,680 debenture-holders, making a total of 8,401 partners in the concern. There were so many points of interest in connection with the report and accounts that he hardly knew how to tackle them. Beginning with the first paragraph of the report, which, after all, contained the kernel of the nut, the year in respect to which these accounts were presented had been one of progress—in the sense, at all events, of spending the shareholders' money freely, for reasons which he would enlarge upon as he went along. The facts were fully set out in No. 1 account, and comprised the gist of the observations which he would have to make on the subject. They would see on the debtor side of the account very considerable additions in the form of several new undertakings. The policy of the Board for the last few years had been to bring into brotherhood all the subsidiary companies. The amalgamation with the three great companies which became the National Telephone Company (Limited) showed them the wisdom of fusion so strongly that they had from time to time, as opportunity offered, induced the other companies which were even less important to join this Company, with the result that they were now practically all absorbed. They would see a small number of names of these undertakings in the capital account. There was the Western Counties and South Wales Company (Limited), which was the most important, and which was absorbed at a cost of £277,607. Then came the telephone business of the Sheffield Telephone Exchange and Electric Light Company (Limited), which cost £38,696—an institution in which electric lighting and telephony were combined. The Directors of the National Company did not covet the electric lighting, but they bought the telephoning business of that Company. Some other minor companies were absorbed, all of which brought up the total to the not inconsiderable sum of £345,776. The result was that areas, not before within their government, were now brought into it. The business was progressing, and the subscribers increased in number. The peculiarity of this business—he did not know that it was a peculiarity—was that every single new subscriber meant a special outlay. It was somewhat different from other enterprises, like a railway, which involved a large first cost, as to which they knew how they stood. The peculiarity consisted in this, that money had, from time to time, to be advanced three, four, and six months in advance of the completion of the work which produced their income. The other capital charges amounted to £305,799. That was a very large sum of money to spend in the course of the year—£651,575—and that money had to be provided. It was provided by the issue of certain of their stocks amounting to £595,000 in round numbers, and these subscriptions, of course, brought upon the year certain charges which made their influence felt when they came to the net revenue account. The Directors in their report called attention specially to the large expenditure in the acquisition of the other companies. They said that it was policy to do it, and although it had entailed a large amount of outlay they were prepared to take the responsibility of having done so, believing that they would have the approval of the shareholders for their action. There were some other charges which he would have to advert to later; but having got into their minds the foregoing facts, he would pass on to the consideration of what had been done during the year. Of course he need hardly say that money spent in the way described—that was to say, either in the acquisition of other companies or in the extension of the Company's business—was not immediately productive. It took some little time to bring about results. He did not think that they had done badly, because if they turned to the net revenue account it would be seen that there had been a considerable addition to the business of the Company. He had occasion at the previous meeting to impress upon the shareholders the necessity of finding some principle or factor by which they could measure approximately their exact position. In a railway company it was the train mile which was a familiar thing to them that determined it, as it was of a fixed significance. They had tried to find some method of fixing a standard of comparison, and the nearest approach to that was the wire, not the subscribers. Some subscribers, it was true, used more than one wire, some having two and others three; but each wire entailed a specific expenditure, and a multiplication of wires meant a multiplication of business; and therefore a wire might be looked upon as an instrument by which comparisons might be made. It was the nearest thing that they could find by analogy to the train mile of a railway. The progression of wires, of course, was, therefore, one of the means of measuring the progression of business, and in the year they had increased from 47,878 to 59,631 wires, or a difference of 11,153. He must qualify that by reminding them that they brought in during the period under review the *corpus* of the Western Counties, &c., Telephone Company, and when it was taken over it had about 4,000 wires, and deducting these, the normal progression of business had been 7,153 wires in their area during the year. It was just as well to dispel illusions which existed in the minds of some people outside, as to what it meant to put on a new subscriber. The average cost was something like £42 per subscriber per wire. Some people had an idea that it could be done for much less. In their undertaking he believed that the experience and skill at their command enabled them to tell exactly the right thing to do, and to do it in the most economical and best fashion possible, and that was the figure at which it worked out. Coming to the paragraphs in the report, he believed that the language contained therein was almost exactly the same as that used in preceding reports—it was only the figures which were altered. The income accrued in respect of the business of the year amounted to £583,590, which was an increase of £119,848 over that of the preceding twelve months. He must remind them again that both the Sheffield Company and the Western Counties Company were included in the account, and their income, which subsisted last year before they came into the scheme of amalgamation, was incorporated bodily in the account. The rentals carried forward this year for unexpired terms of running contracts amounted to £285,020, or an increase of £50,649 The working expenses and other charges, excluding debenture and other interest, had increased by £75,392, which was a very large advance in proportion to the increase of business, namely, £119,848. Like the income of the Western Counties and the Sheffield Companies which came in to swell the gross receipts, the expenses connected with the new areas contributed to swell the working expenses, and with this disadvantage that those areas were more sparsely populated. The income per subscriber therefore was relatively less, and the outlay was relatively more in the bigger undertaking. To this extent, so to speak, the averages were diluted. The net result for the year, after deducting the Post Office royalties amounting to £54,220, which was a pretty stiff tax to levy on a Company like this, was a profit balance of £217,725, or an increase of £30,475 over that of the preceding twelve months. They were always being pulled to pieces because they did not reduce their tariffs. Most of them had a slight interest in that, but the reduction of tariff meant that their expenses were not diminished, and he wished proprietors to turn that over in their minds and master it. They had to remember that all reductions came out of one pocket, namely, profit, and in this enterprise, although he believed that it was very sound, and its future might be looked upon as assured, a small reduction might have a very large effect on the dividend; and if they took the figures before them to pieces it would be found that they were not in such a position as to be enabled to make any very great reduction. He did not know why this Company and its service deserved all the odium frequently cast upon them by the unknowing. The curious thing about such undertakings was that people who knew nothing about them were always ready to dictate what ought to be done. Such people were not concerned as to whether what they suggested was either wise or economical. They contrasted the state of things in New York, Boston, St. Petersburg, or Berlin, in which the circumstances were so entirely different as to produce a very serious effect upon profit. He would give a few figures which spoke eloquently in favour of

Digitized by Google

the Company since its fusion. The first year's business—that was to say, in 1890—realised an average receipt throughout the year from those served by the Company of £14. 11s.; while in 1893 the average was reduced to £9. 17s. 9d., and he ventured to say, with the greatest respect to all critics, that there was no comparison between that charge and that of any other great city in Europe, not even including Berlin. In 1890 the proportion of expense was 49½ per cent., while this past year it had been 62 to 65 per cent. of the revenue. The reduction came out of their pockets; further expenses were relatively a fixed figure. The number of lines had increased from 36,000 to 39,131, and, as they knew, the dividend was 6 per cent. Was 6 per cent. an unreasonable return in such a venture as theirs? Let them think of the danger they had undergone in making a new business, and under such disadvantages as he supposed no other commercial company had ever experienced. They could not compare their undertaking with those of other great cities. Let them take Paris, if they liked, or St. Petersburg, Vienna, or any other city where telephonic business was carried on, all of which, by way of comparison, were cast in their teeth. He would very much like to dissect the accounts of some of the companies doing business there as he dissected those of the National Company. He was sure that he would make out that many of them must be worked at a loss, and not at a profit. In London everybody said what a scandalous thing that people paid absolutely £20 for their service. This was perfectly illusory, because if those people chose to pay for a term they could get their service for less. It was surely not unreasonable to charge a high rate for a service for a short time. The average cost for the past year had been £15. 0s. 7d. per assured tenancy, which could not be compared with the charges in some other cities. London was three times as big as Paris, and proportionately much larger than the other cities which he had named, and the whole area was included in a subscription, and the work was carried on under extreme disadvantages. Amongst others was that in London they had to pay £1. 4s. for wayleaves for every wire. In Berlin, in Paris, and in many other cities he knew they did not pay much for wires. This Company paid to the Post Office £1. 6s. 9d. by way of royalty, and he maintained that, looking at the area covered and the circumstances under which the business was carried on, London was the cheapest city in the world. He was willing to accept the challenge of any expert on the figures, if such a one were bold enough to challenge them. The net result for the year, after deducting the royalties referred to, was an increase of £30,475. Now what were they going to do with this balance? They proposed to pay a dividend of 5 instead of 6 per cent. for prudential reasons. They could, of course, have paid 1 per cent., more, but they had to consider the character of the business, and whether it was not a prudent thing, and such as commended itself to men of sense, to pay a dividend—not so bad as these times went on and consols diminished in value—which they could maintain and which would put them in a stronger financial position. The Directors did not ask the shareholders to accept a smaller dividend with a light heart, but they came to the conclusion that it was their duty, having a fuller knowledge of the circumstances of the past and present and those that were likely to arise, to recommend, if not to urge upon the shareholders to accept the reduction. He thought that he had said enough about the financial part of the business, but he would be glad to answer any questions that might be asked on the figures. He now came to paragraph 8 of the report, referring to the acquisition by the National Company, partly by purchase and partly by the exchange of the New Company's shares for National shares, of nearly the entire interest in the New Company. The paragraph, he said, disclosed the whole story of the transaction. They were in the midst of the negotiations under which they were to become partners to a certain extent in the undertaking alluded to when the policy of the Government was commenced. The late Duke of Marlborough, who was a most capable man and the moving and enthusiastic spirit of the New Company—and who would not take no for an answer—was extremely opposed to what the Government was to do. He was brought into close contact with the Directors in considering what was to be done, and the best thing that he saw was to fuse with this Company. The universality of this business and its administration was so apparent that competition in it meant disruption. The Government had the right of taking over the telephone enterprise any day it liked by agreement, and so far its action meant disruption, which seemed to be the policy of some Governments; but they had not done so, but had elected that the Company should go on, but they were uncomfortable that they had not got their fingers in the Company's pie, and decreed that the most difficult and costly part of the business should be committed to the Company, but that they should keep the arterial part of the business in their own hands. They were, in fact, going to have two departments to do the work of one. The negotiations had been somewhat protracted, for he did not think that the Post Office exactly understood the position; but the Company had been forced into the policy it had adopted. Paragraph 10 spoke for itself. Their business was becoming very extensive, and it would still further extend. They had many critics, it was true, but they had many friends, and they had to do very delicate work. The rapid growth of the business of the Company, and the increasing responsibilities of the Board, involved in the closer relations with the Post Office, induced the Directors to make some change in the Directorate by importing into it some gentlemen of public position and experience. That, of course, was not done without some sense of regret, for all the members of the Board worked so harmoniously together, and their work was very fascinating. Indeed, he had never known anything so fascinating as telephony. He could not get away from it. He thought that the thanks of the proprietors were due—and he was sure they would be readily accorded—to Messrs. John Bruce and Peter Garnett for the self-sacrifice they had made by their voluntary retirement from the Board so that it might secure the services of Lord Balfour of Burleigh and Sir Albert K. Rollit, M.P., who could not fail to be a great acquisition to the Company. He concluded by moving the adoption of the report and accounts, and the payment of a dividend for the half-year at the rate of 6 per cent. per annum (tax free) on the First and Second Preference Shares, and 5 per cent. on the Third Preference and Ordinary shares, making the dividend for the year 6 per cent. on the First and Second Preference Shares, 5 per cent. on the Third Preference Shares, and 5 per cent. on the Ordinary shares.

Lord BALFOUR, in seconding the resolution, said that after the exhaustive speech of the Chairman on the last year's work of the Company, there was very little for a comparatively new comer like him to enlighten the shareholders upon. At the same time, after the kindly way in which his name as a Director had been received, it would be ungrateful if he did not in a word or two say with what pleasure he had joined the Board of the Company, and taken a small part of its management. He came into it, as the Chairman had said, with a fresh mind looking at things rather from an outside point of view. But he would like to say once for all that although he had been engaged in some other enterprises he had never associated himself with a body of gentlemen more harmonious among themselves or more energetic or single minded in the service of the concern which they had undertaken to direct. He quite felt the fascination for the business to which the Chairman had alluded, and he hoped that with a little more experience he might be able to do good work in the interests of the Company and his own, which were identified with the Company. The Chairman had alluded to the progress which the business had made during the last year, and said that it was progress to some extent made up of the spending of the money of the shareholders. But the expenditure had had some definite results. He thought that it meant the providing of the material for the service of the Company, not only in London, but in many of the most populous parts of the provinces, and it had had also a most gratifying result in extending and developing the business acquired in previous years. He did not think that the Chairman had said enough about the complexities and difficulties which the officers of the Company had had to face in managing the London business. It was all very well to compare London with Paris, Berlin, or Vienna, but anyone who had studied the matter knew that with a business of this kind London stood alone. No city presented such complexities in the matter of telephony as the metropolis. They had got, he believed, a sound and a steadily-increasing business, which, in his humble opinion, required only care and forsesight to develop it into a prosperous property. It was not every company that could claim after so short a history to pay £54,000 by way of royalties and yet be able to declare a dividend. He thought that that was a very severe tax, but it was a condition imposed on the Company, and it said something for the energy of the officers that the Company was able to pay it and maintain a dividend of 5 per cent. Something had been said about the exhorbitant charge of £20 for the service, but let them think what they got for the service compared with what it would cost to conduct their business by the telegraph instead of the telephone. What could they do for £15 by the former in the course of a year? He cordially supported the resolution of the Board to pay only 5 per cent. instead of a 6 per cent. dividend because he thought that to pay a steady distribution of that kind would be a careful regard to the necessities of the future was the wisest course which they could pursue. That was the course which the Board recommended to the proprietors

The CHAIRMAN, in reply to the Rev. M. BLACK, explained that the item £397,580 represented the cost of acquiring the shares in the New Telephone Company (Limited). They subscribed a third of the original capital, and since then they had availed themselves of acquiring nearly the whole of the existing interest. What they had got in return was a business of that Company in Manchester, and that of one or two small centres outside that City, and certain agreements in London said to be of very great value. With respect to the reserve fund he thought that it was very fully discussed at the last meeting. Some companies when they put aside a reserve fund invested it and set it out in their balance-sheet as being locked up in this, that, or the other security. The Directors of the National Company had invested theirs so far in their business, partly as a matter of judgment and partly from the circumstances of their position. If they had to raise, say, £130,000, for the purpose of extending their business, they would have probably to pay somewhat more for it than by putting it to a reserve fund. They were extremely well represented in Glasgow, where the Corporation was moving in the direction of establishing a local telephone.

A SHAREHOLDER asked whether the £397,580 was money paid out of pocket.

The CHAIRMAN replied that it represented money subscribed to acquire the business of the New Telephone Company (Limited).

Mr. LEAK asked what would happen when the licenses of the Company expired.

The CHAIRMAN replied that some provision would have to be made against that contingency. Hence the necessity for paying a small dividend and having a big reserve. What he thought was that they would be disposed of by absorption by the State.

The motion was then put to the meeting, and carried unanimously.

The retiring Directors, Lord Balfour of Burleigh, Sir Albert Kaye Rollit, M.P., Mr. Charles Swain Agnew, and Mr. George Hunter Robertson, were then severally re-elected to their seats at the Board. Each of these gentlemen expressed his acknowledgment for the compliment, Sir ALBERT ROLLIT taking occasion to remind the meeting of the great interest which he has taken in telephony since its introduction into this country. He further wished to confirm the remarks of the Chairman in reference to the late President, the Duke of Marlborough. He thought that there ought to be no difficulty in reconciling public and private interests in the matter of telephony, and the best way to secure this object was to give an efficient service.

The auditors (Messrs. Welton, Jones, and Co.) were afterwards reappointed, and a cordial vote of thanks having been accorded to the Chairman, who gracefully acknowledged it, the proceedings terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

ELECTRIC AND AUTOMATIC ENGINEERING COMPANY (LIMITED).—This Company was registered on the 15th inst., with a capital of £10,000, in £1 shares, to purchase or otherwise acquire any patents, patent rights, licences, inventions, or other privileges, for any system or process for the working of automatic supply boxes or machines, by mechanical, electrical, or other power, and for the production of electric currents, to manufacture, sell and deal in chemicals for the generation of electricity, and to develop and to turn to account the said patents.

GRAVIER DYNAMO SYNDICATE (LIMITED).—This Company was registered on the 13th inst., with a capital of £10,000 in £1 shares, to enter into an agreement with Alphonse J. Gravier, for the acquisition of certain patents, inventions, and patent rights, particulars of which do not transpire, and generally to exploit and turn to account the same.

JAMES CARMICHAEL AND CO. (LIMITED).—This Company has been registered with a capital of £65,000, divided into shares of £10 each, to acquire and conduct the business of engineers, ironfounders, boilermakers, &c., in Dundee, carried on by James Carmichael and Co.

MANCHESTER STEEL NUT AND TUBE COMPANY (LIMITED).—This Company has been registered with a capital of £80,000, in £10 shares, to acquire the business of steel nut and tube makers in all its branches, as now carried on by Edward Cope, under the style of the Steel Nut and Tube Company, and to develop and extend the same; also as mechanical, electrical, hydraulic, and marine engineers, tool makers, &c., &c.

STANNUM METAL COMPANY (LIMITED).—This Company was registered on the 15th inst., with a capital of £40,000, in £1 shares, to acquire and exploit the British patents of C. L. C. Bertou, in connection with an improved process for the recovery of tin and iron from waste clippings of tinned sheets, and also for improvements in the process of precipitating oxide from acid solutions containing same with other metals, and to carry on the business of mechanical engineers, machine, and general tool makers, electrical engineers, electricians, suppliers of electricity, and manufacturers of appliances used in the generation, supply, distribution, and employment of electricity.

WEST INDIAN DEVELOPMENT COMPANY (LIMITED).—This Company was registered on the 13th inst., with a capital of £5,000, in £1 shares, to enter into an agreement for the sale to the Company of a concession made to J. K. D. Mackenzie, by Act of Parliament, to enable him to supply electricity for the purpose of lighting the City of Bridgetown, in the Island of Barbados, and to carry on (*inter alia*) the business of electricians and electrical engineers.

ANDREWS AND PREECE (LIMITED).—The 1893 return for this Company, recently filed, shows that while the nominal capital is £25,000, divided into 300 Deferred shares of £10 each, and 2,200 Ordinary shares of like value, only 418 Ordinary and 300 Deferred have been taken up. All the Deferred and 226 of the Ordinary shares have been taken up. The full amount has been called on the remaining Ordinary share capital, resulting in a payment of £1,865, and leaving £55 as yet in arrears.

CAMBRIDGE UNIVERSITY AND TOWN ELECTRIC LIGHTING COMPANY (LIMITED).—When the last return was filed on the 10th inst. only the shares of the seven original signatories were taken up, no calls having been made.

CHINA AND JAPAN TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to May 30, 1893, has been filed. Out of a nominal capital of £20,000, in £1 shares, 14,761 have been taken up, of which all were issued as fully paid. The Oriental Telephone and Electric Light Company (Limited) hold 14,101 of these shares.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 16, 1893, has been filed. The nominal capital is £100,500, divided into 14,000 Ordinary and 6,000 Preference shares of £5 each, and 500 Founders' shares of £1 each; 9,277 Ordinary and 500 Founders' shares have been taken up, of which 5,666 Ordinary and the whole of the Founders' shares have been issued as fully paid. The full amount has been called, and £18,055 has been paid on the remaining 3,611 Ordinary shares.

CROMPTON-HOWELL ELECTRICAL STORAGE COMPANY (LIMITED).—The annual return of this Company for 1892, made up to August 17, 1892, has recently been filed. The nominal capital is £19,600, divided into six Founders' shares of £100 each, and 19,000 Ordinary shares of £1 each. All the Founders' and 12,006 of the Ordinary shares have been taken up, the full amount called on the Founders' shares, while a call of 15s. per share has been made on the Ordinary shares, resulting in a total payment of £9,604. 10s. The return for 1893 made up to March 25th and also recently filed, exhibits no change from the foregoing.

CUTTRISS, WALLIS, AND CO. (LIMITED).—The second annual return of this Company, made up to June 16th, and recently filed, shows that 771 of the 2,000 shares of £5 each have been taken up; 420 shares have been issued as fully paid, while the full amounts have been called, and £1,755 paid on the remainder.

DALZIEL'S ATLANTIC TELEGRAM COMPANY (LIMITED).—The annual return of this Company, made up to May 16, 1893, and recently filed, shows that 150 fully-paid and 73 "subscribed" shares of £100 each have been taken up out of a nominal capital of £25,000. Upon the "subscribed" shares a call of £50 per share has been made, resulting in the payment of £3,850, leaving £50 in arrears; while £50 has been paid in advance of calls.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended June 30th last of 12s. 6d. per cent. on the Ordinary stock and 25s. per cent. on the Preferred stock, less income-tax, payable on August 1st to stockholders registered on the books of the Company on the 10th inst.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 16th were £774, as against £766 for the corresponding period of last year, being an increase of £8. The total receipts for the half-year amount to £1,843, against £1,499 in the corresponding period of 1892, being an increase of £344. For the past half-year the accounts show a balance, after providing for the Debenture interest and the full dividend on the Five per Cent. Preference Shares, sufficient to allow the payment of a dividend on the Consolidated Ordinary Stock at the rate of ¾ per cent. per annum, against ½ per cent. for the corresponding period of last year, leaving £898 to be carried forward.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have decided to recommend a final dividend of 3s. 6d. per share, free of income-tax, to be payable on and after the 29th inst., making, with the interim dividends already paid, 3½, per cent for the year ended June 30th last. After placing £3,000 to reserve fund account, a balance of £819. 2s. 4d. is carried forward. The transfer books of this Company will be closed from the 14th to the 28th inst. inclusive.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons of their Five per Cent. Debentures, due August 1st, will be paid on and after that date by Messrs. Glyn, Mills, Currie, and Co., 67, Lombard-street, E.C. Coupons should be left three days for examination.

EDINBURGH ELECTRIC SUPPLY CORPORATION (LIMITED).—At an extraordinary general meeting held on Tuesday, the resolution passed a month ago, voluntarily winding up the Company, was confirmed.

EUROPEAN GAS COMPANY (LIMITED).—The annual general meeting of this Company was held on Monday last at the offices, Austinfriars, E.C., with Mr. J. Blacket Gill in the chair. The Secretary and General Manager (Mr. Williams) read the report of the Directors, which stated that the Company's business had been well maintained during the year. There had been a falling off in the consumption of gas at Boulogne and Nantes, where the competition from the electric light had been felt somewhat severely; but the Directors had reason to hope that the decrease at these stations was but a temporary one, for in other towns—notably, Amiens, Rouen, and Havre—they were able to report a considerable increase of business, in spite of similar competition. In connection with the development of electricity the Board would remind the shareholders that every effort was made to extend the use of gas for cooking, heating, and motive-power. The Chairman, in moving the adoption of the report, said he thought they might congratulate themselves upon the increase of 1 per cent. in their rental. He had paid a visit to their stations during the past year, accompanied by the General Manager. He had not previously been for two years, and he was very much struck to notice how greatly the electric light had gained ground in the interval. There were very few shops of importance which were not lighted by electricity in the towns which their Company supplied with gas, excepting Cannes, and this competition, of course, they felt very keenly. The *cafés* were large consumers of the electric light. Many of the people would say that they paid more for electricity than for gas, but that they were compelled to follow suit when their rivals adopted the electric light. They had about 38,000 stoves on hire, as well as 250 gas-engines, with the result that about 25 per cent. of their total consumption was in the day-time. So far, this was a class of business with which electricity could not interfere.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—The interim dividend warrants for the past half-year on the First Preference shares at the rate of 6 per cent. per annum have been posted. An interim dividend on the Ordinary shares at the rate of 4 per cent. per annum will be payable on the 31st inst.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The second ordinary general meeting of shareholders of this Company was held on Thursday last at the offices, in Commercial-street, Sheffield. The Chairman, Mr. George Franklin, said that in view of the growing demand for the electric light it had been found necessary to rebuild and enlarge the central station in order to make room for new steam and electrical plant, which would be of the most modern description, and would probably be at work during the autumn. The station would have an ultimate generating capacity of 80,000 lamps. Twelve and a-half miles of underground conduits had been laid in the streets for the reception of the distributing cables. The prospects of the Company were most encouraging, and a new issue of 4,000 Ordinary shares would be probably made in the near future. A dividend of 5 per cent. per annum was declared, free of income-tax, and the retiring Directors were re-elected.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD.).—The transfer books of this Company will be closed from the 17th to the 25th inclusive, preparatory to the payment of an interim dividend of 12s. per share to shareholders on the register on the 17th inst.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 14, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,346.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the two weeks ended July 15th were £1,880, as compared with £2,084 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 793.—Vol. XXXI. FRIDAY, JULY 28, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

In spite of its very modest dividend, the City and South ondon Railway continues to show satisfactory progress, and hough the total receipts (£23,159) for the first six months the present year are nearly 8 per cent., the passengers rried (3,146,656) nearly 12 per cent., and the train mileage 17,664) over 15 per cent. more than was the case this time t year, the total working expenses are £14,964, as against 5,098. The item of most interest to electrical engineers, e "locomotive and generating" expenses, has come down a most encouraging manner. When the line commenced eration these expenses were 9d. per train mile, this time st year they were 7·7d., this year they are under 6½d.

We have watched with no little interest the telephone-tube ying enterprise of the City of London Electric Lighting ompany, rejoicing to see two hitherto rival branches of the ectrical industry joining together to their mutual benefit id profit. At the same time we were curious as to the way which the Corporation would regard this union of interests. To take advantage of the privileges conferred after any years' negotiation upon an electric lighting company quietly run a network of telephone tubes was an excellent roke of business, and to get this *coup* blessed, so to speak, y an Act of Parliament was a still more brilliant achievement. It is, how ever, always dangerous in this country to trifle ith established institutions, and none the less so when they appen to be ancient municipal institutions; and the report f the Streets Committee, which was carried at Tuesday's neeting of the Commissioners of Sewers, is an illustration of his fact. As the matter now stands, sanction will not be given to the running of telephone wires in the tubes already aid, unless good instruments, double-wire circuits, and £8 entals are promised. This is, indeed, a vigorous push for an efficient and cheap telephone service, but we should like to know by what process the Streets Committee arrived at that £8. Was the formula by any chance:—Divide present rentals by two, and deduct £2 for injury done to corporate dignity?

The opposition which the National Telephone Company offered to the insertion of the Model Clauses in the Dublin Southern District Tramways Bill had considerable justification. The Telephone Company and the Tramway Company having already come to terms as to the clauses to be inserted, the former naturally objected to the substitution of other classes less favourable to itself, which were, as yet, unsanctioned by Parliament and in an embryonic state of development. Its final acceptance therefore of the Model Clauses suitably modified to meet the special circumstances of this particular case, may be taken as a sign that it recognises that the day is past for getting the telephones protected without regard to other considerations; although, acording to Mr. Pember, the National Telephone Company does not propose to peaceably permit the general adoption of the Model Clauses; "they wished to preserve their full freedom of opposing the Model Clauses on their merits or demerits at any future time."

The valid objection that it was impossible to adopt the Model Clauses because the Board of Trade regulations, their necessary appendages, were as yet non-existent, was got over at the Telephone Company's suggestion by so altering Clause 8 as to make any regulations that the Board of Trade might make in future of the same effect as if included in a schedule of the Bill under consideration. Again, the National Telephone Company urged in regard to the clause containing the proviso that it was after a certain number of years to have no ground of complaint against electric tramways unless the telephone circuits had been double-wired, that this proviso and Recommendation 6, suggesting the grant of statutory powers to run underground telephones, must be taken together, so that until the statutory powers were given it would be unfair to put the proviso in force. In the end, three years' grace was given to the Telephone Company, and the Board of Trade was empowered to extend the term, if necessary. A compromise which seems at once fair and practicable. From what has taken place in connection with this Bill, and the difficulty which is being raised in connection with the insertion of the Model Clauses in other tramway Bills, it is evident that the sooner Parliament confirms these clauses, and the Board of Trade draws up its regulations, the better—especially in view of the fact that it has the power to alter any regulations which, upon trial, prove impracticable.

The investigation by Dr. Sumpner on the action of combinations of coils and condensers when used with alternating currents, which will be found in our columns this week, is one to which electrical engineers may profitably turn upon the

Digitized by Google

advent of the commercial condenser. Indeed, not only in that distant point of time—for commercial condensers suitable for high-pressure working seem to be a long time a-coming—but at the present, there is much of practical value in the general investigations and the useful set of curves which Dr. Sumpner contributes. It is to be regretted that there is the tendency, which he points out, on the part of mathematicians, to assume in their investigations values which are wide of those occurring in practice. For any conclusions arrived at in such a manner, however sound from a theoretical point of view, must fail to appeal to the practical engineer. There is no necessity for us to cite particular instances, where an alteration of the chosen values will make a vital difference in the character of the results; mathematicians are very familiar with them. One of the merits of these investigations is the entire absence of arbitrarily chosen magnitudes of this sort, and the wide range of practice over which the curves are consequently applicable.

We publish this week some details of an electric locomotive which has made its appearance in America. We regret that some of our American contemporaries have adopted an attitude of such jubilation over its introduction. The locomotive may be a creditable piece of work, but only a very little investigation of its capabilities will reveal that such expressions as "high-speed locomotive," and prophecies of the imminent millenium of electric railways, are quite out of character. In fact, when compared with a mere steam shunting engine, this "first practically operative high-speed electric locomotive in the world" (*sic*) must take quite a second place.

What is it that we really have in this wonderful engine? The draw-bar pull of 12,000lb. and the speed of 30 miles an hour look excellent, as, indeed, they would be if we could have both of them at the same time. But, unfortunately, we cannot; and, indeed, it is doubtful if we could have a 12,000lb. pull at all without finding the four driving wheels skidding violently on the rails. To give an adhesion of 12,000lb. the rails would require to be on a dead level and well sanded, unless the gross weight of the locomotive could be increased to considerably above 30 tons. On a gradient of 2 per cent. it is doubtful if the engine could start on more than 8,000lb. with an average condition of the track. Taking the normal starting effort at 10,000lb., there could hardly be more than one-tenth of this at full speed, even with the series-parallel device for starting the armatures. This would haul a load of about 80 tons on a dead-level track in good condition and with a fair side wind. With a bad state of rail, or against a high head wind, or up a stiff railway gradient, the capacity of haulage would be considerably lowered; and inasmuch as these conditions have to be allowed for in practice, it would seem nearer the actual mark to rate the locomotive as having about 30 tons capacity of haulage, over gradients not exceeding 1 per cent. Within the limits of adhesion it would, of course, always be possible to "link up" the locomotive to a higher load, at a sacrifice of speed and efficiency; just as, within the same limits, it is possible with a steam locomotive. But the practice would be vastly more wasteful with an electric locomotive than with its brother of the water vapour. In fact, it would never be tolerated by an experienced engineer, except occasionally over short lengths of steep gradient.

The proverb that a man must tell a second lie to hide a first seems to have its counterpart in engineering practice, for it is certain that if he once persuades himself that a certain piece of bad practice is good, he will be compelled to label "good" every other atrocious practice which is necessary to cover up the defects of the initial error. Once believe that black is white, and every raven is mistaken for a swan. The American practice of designing railway tracks to go round absurdly sharp curves and, sometimes, up sharp gradients at the same time, has its inevitable evil reaction in the design of locomotives and coaches. We cannot expect a coach with a stiff backbone to set half of itself almost at right angles to the other half, so we must give it the flimsiness of a centipede by some such arrangement as the "radial truck" which is in so much favour in America just now. The fault does not so much attach to the truck itself as to the line for which such a defective truck is necessary. The principle involved is equally applicable to other branches of engineering. Bad practice leads to more bad practice, whether in the design of railways, steam engines or dynamos. What, to cite another example, could be more reprehensible than the practice of designing a wasteful steam engine to "suit" a badly constructed dynamo?

We could wish that more town councils were able to discuss the *pros* and *cons* of municipal electric lighting in the sober business-like tone which characterised the debate on this subject at the last meeting of the Birmingham Town Council. The usual references to the "countless benefits to thousands yet unborn" likely to accrue from municipalising electricity supply may be eloquent, but they certainly are not argument. At Birmingham, however, they have sense enough to see that there need be no fear of monopoly, nor, when the time comes for purchase in after years, of extortion. They also realise that whilst under the best conditions the business of electricity supply is a paying one, it is by no means generally so; and, consequently to undertake it would be largely a leap in the dark. Now speculation, whether municipal or metaphysical, is sadly unprofitable.

An esteemed technical contemporary does not like the common modes of talking about electrical things, and it exhausts an inordinate number of editorial notes in saying so. The sum of its objections seems to be that electrical terms do not convey to it the same ideas that they do to every electrical engineer; and the claim which it bases on the objections is that electrical engineers should forthwith and for ever stop using these electrical terms. "Passing current" is, for instance, a term which is to be tabooed, and, by implication, we suppose, the terms "stopping current" and "starting current." In fact, if we must be metaphysical, there is far more objection to the last two named phrases than to the harmless one, "passing current." For how can one start a current when there is not a current till

Digitized by Google

it *is* started; or how can a current be stopped when in the very act it ceases to be? Instead of saying that "so much current" has passed through a cell, the expression "so much electricity" is recommended. This rather makes matters worse. The expression "current" is unfortunate, but is at present unavoidable; but the expression "electricity" in the sense of a quantity like energy or heat is almost as bad, and is easily avoided.

ELECTRICAL litigation in this country is, it must be confessed, a trifle dull, notwithstanding the amusing episodes which now and again arise owing to the tergiversation of experts whom our lawyers persist in treating as ordinary, every-day witnesses, although they are, as a matter of fact, and from the very condition of things, as full of bias as an egg is of meat. According to our New York correspondent's account of the latest development of the incandescent lamp litigation, however, they manage these things differently in America. GOEBEL, whom we were led to believe made commercial glow lamps before the Flood, only made them, one of his sons now swears, just in time for a recent trial. Other witnesses appear also to be going back upon all their previous sworn statements, and some of them seem likely to cross over from the civil to the criminal Courts. This is, indeed, exciting, but even with the dull season full upon us, we are glad the centre of disturbance is as far away as Milwaukee.

The Cost of Patenting.—To patent an invention throughout the world would cost something like £3,000.

Cable Interruption.—

	Date of Interruption.
Paramaribo—Cayenne	April 15th.

Hull.—At the last meeting of the Town Council Mr. A. H. Gibbings, electrical engineer to the Hove Commissioners, was elected to a similar post at Hull.

The West Hartlepool Time Gun.—On Monday, last week, the West Hartlepool time gun, which is fired by electricity from Greenwich, went off at five minutes to one o'clock, a flash of lightning having undertaken the duty.

European Electric Traction Statistics.—The electric tramways and railways of Europe now amount to about 270 miles, of which 105 miles are in Germany, 50 miles in the United Kingdom, 55 miles in France, and 25 miles in Switzerland.

Prof. Garnett.—Prof. Garnett has resigned his position as principal and professor of pure and applied mechanics at the Durham College of Science, to become Director and technical adviser to the Technical Education Board of the London County Council.

Municipal Telephony in Blackburn.—The Blackburn Corporation has just had fitted up for it a telephone system of 25 stations, connecting the Municipal offices, Police stations, gas-works, &c. The instruments used are Hunning's transmitters, and double-pole Bell receivers.

Atlantic Telegraphy.—The Commercial Cable Company announce that on June 13th, between the hours of 6:54 a.m. and 4:42 p.m. (9 hours 48 minutes) 807 messages were passed in one direction over one of this Company's main Atlantic cables, 2,388 miles long, being an average of 82·2 messages per hour.

Kingston-on-Thames.—The Electric Lighting Committee of this Borough are prepared to appoint a resident electrical engineer to take charge of the construction of the works for their electricity installation, and to have the management of such works when completed. For further particulars see our advertisement columns.

Eastern Telegraph Company.—This Company notifies that code messages may be accepted for Pernambuco at senders' risk, subject to receivers producing translations for inspection there. The prohibition of code by the Brazilian Government to all other parts of Brazil continues in force, but non-political plain language messages are delivered without restriction.

Rats and the Trolly.—It is stated that in some parts of Brooklyn there is a plague of rats owing to the exodus of the rodents from the car stables, the trolly having already supplanted about 2,100 horses on the Brooklyn City Railroad, which now has about 400 trolly cars in operation. The rats have therefore deserted the stables for better feeding quarters.

The Telegraphs.—In answer to a question, Mr. Arnold Morley stated in the House of Commons on Tuesday evening that comparing the total business done by the department in telegraph messages in 1892-3 with that done in the previous year, it would appear that the business was almost stationary. Any permanent addition to the force of telegraph operators under such circumstances was a matter which required serious consideration.

Mean Density of the Earth.—According to the latest determination of the mass and volume of the earth, by M. Berget, it would appear that the specific gravity of the earth may be taken at 5·4. The mass of the earth is given as $5{\cdot}85 \times 10^{27}$ grammes, and the constant of attraction as $6{\cdot}5 \times 10^{-8}$. Comparison between this constant and that for the attraction between magnetic or electric unit quantities will show how remarkably minute is the measure of the gravitational force between two unit portions of matter at unit distance apart. That this constant is independent of the nature of the atom is one of the standing wonders of molecular physics.

The Liverpool Tramways.—At the recent half-yearly meeting of the shareholders of the Liverpool United Tramways and Omnibus Company, Sir David Radcliffe, the Chairman, stated that the present lease had only about 11½ years to run. He mentioned that, he said, because it was the intention of the Directors to make another attempt to apply electric power as a means of haulage. Of course, before they could entertain the idea of building new cars and adapting them for mechanical appliances, they would seek an extension of the lease, as the capital outlay consequent upon a thoroughly different and new equipment of cars would be a very costly one, and one that could not be faced on a lease of only 11½ year's duration.

Government Grant to the Royal Society.—Among the numerous appropriations of the sum of £4,000, which is annually voted by Parliament to the Royal Society for the advancement of science, we notice the following which have been devoted to electrical research:—To Mr. R. P. Chattock, £10, for an investigation of the absolute measurement of the charge conveyed by the ions of an electrolyte; to Prof. C. G. Knott, £50, for an investigation of the effect of magnetism upon the internal volume of iron, steel, and nickel tubes of various bores; to Mr. H. L. Callender, £80, for a comparison of platinum and air thermometers; and to Prof. Dewar, £300, for his researches on the physical properties of liquid and solid oxygen, nitrogen, and air.

The Sims-Edison Electrically Controlled Torpedo.—Reports from Toulon give some account of experiments lately made there with the Sims-Edison torpedo by a special commission appointed by the Minister of Marine. On the 12th inst. the commission had three buoys moored at sea some distance from the Caraque battery, and the engineer of the Company was requested to steer round each buoy in succession, the object being to test the steering capacity of the torpedo. The sea was so rough that a successful result was hardly expected by the commission. However, the order to start was given, and it was then seen that the engineer had complete control of the weapon. The torpedo passed close round the first buoy, then round the second buoy, and then round the third. The Admiral ordered the torpedo to be stopped short and again started for the point of departure, which was done. During the run the torpedo appeared in no way troubled by the high sea. The length of cable paid out was 1,650 yards, the speed 11 knots, and the depth of water 180ft. On the 19th inst. a trial of speed was made; the sea was high, but a range of two miles was covered at a speed of 16½ knots. Although these trials, like previous ones, show the Sims-Edison torpedo to be eminently controllable, its speed is

Digitized by Google

low and the maximum distance to which it can run is short. Warships are not likely to come within less than 3,000 yards of the shore nor likely to caught by a 16½-knot torpedo.

The Production of Hydrogen Peroxide in the Electrolysis of Sulphuric Acid.—In the *J. Soc. Chim. Russe*, XXIII., p. 235, M. Kuriloff has published a note on his researches on the production of hydrogen peroxide and of persulphuric acid when dilute sulphuric acid of different strengths is electrolysed, He employed for this purpose an apparatus which permitted the separate collection of the products formed at the two electrodes. The hydrogen peroxide was determined by titration with potassium permanganate, and the persulphuric acid by adding a known quantity of ferrous salt to the solution and titrating back with potassium permanganate. The results of his experiments are: (1) the quantity of hydrogen peroxide formed is very small; (2) hydrogen peroxide and persulphuric acid may be simultaneously formed at both electrodes, but the peroxide is not always accompanied by persulphuric acid; (3) the formation of both products is intimately connected with the concentration. Persulphuric acid only appears when the solution contains over 1 per cent. of sulphuric acid; hydrogen peroxide when the concentration is over 1 per cent.; (4) mixtures containing 3, 47, and 73 per cent. of acid respectively behave differently from other mixtures with regard to the amount of peroxide formed when they are electrolysed. This is considered by the author to be due to the fact that the composition of these solutions approximates to that required by the hydrates containing $(H_2O)_{1.5}$, $(H_2O)_6$, and $(H_2O)_2$, to each molecule of H_2SO_4, since, according to Mendeléeff, all these hydrates exist in solution.

Obituary.—We regret to announce the death of M. Marié Davy, which took place on July 16th at Clamecy, in the Department of Nièvre. Born in the year 1816, M. Davy lived to the ripe age of 77, and, though in later years he appears to have retired from the field of active scientific research, yet in earlier years he contributed many valuable Papers to, and took a prominent part in, the proceedings of the Académie des Sciences. His principal profession was that of an astronomer. Electricians have most cause to remember Marié Davy on account of the mercury sulphate cell which he invented. This was his principal if not his sole invention in the field of electricity; but it has served a useful purpose in its time, though latterly it has been replaced by the silver chloride cell, for accurate work, and by less expensive batteries, for commercial purposes. The object which Marié Davy had in the invention of this cell was the production of a high and fairly constant electromotive force. This he obtained by means of a zinc-carbon pair, the latter element being immersed in a paste formed of the higher or acid sulphate of mercury, a combination which gave one and a-half volts per cell.——We regret to hear that Mr. W. C. Palmer, assistant electrician to the General Electric Power and Traction Company, was drowned in the Thames on Saturday evening last whilst on duty. Mr. Palmer had only recently joined the Company.

St. Pancras Vestry.—A special meeting of this Vestry was held on Wednesday evening last week to consider Mr. Clements's memorandums on the electric light installation, and Mr. Gibb's replies thereto; also to resume the debate on the adjourned joint report of the Electricity and Dusting and Slopping Committees, recommending the combination of the destruction of refuse with the production of electricity, at the station in King's-road. It was resolved that the discussion should take place on the adjourned joint report of the two committees, to which the following amendment had been moved by Mr. Cox: "That the Vestry is not prepared to entertain the question of any other electric lighting installation until the present installation has been in complete working order for at least two years." Mr. Cox said he was not opposed to the electric light installation; in fact, he took a great interest in it, but he desired to see the Stanhope-street station in perfect order before they started another installation, and that the station should be in the right place. He denied that the defects were of a trivial character. The trenches were laid down under the belief that they were air-tight, but they were not—they were constantly being filled with water. The machinery, too, was constantly out of order; the condenser had never been in working order, though it had cost the Vestry between £400 and £500 to repair; there was a crack in the chimney; and the arc lamps could not be taken over because they were not in working order. Let them delay further action for the present, and see in the meantime whether they could adopt one large scheme to supply the whole of the parish. On Mr. Cox's amendment being put it was defeated by 51 to 22. The Committee's recommendation on being put as a substantive resolution was carried without a division.

Electric Car House Construction.—In the United States they have so many electric car houses and so many fires that it has become a question with the fire insurance offices whether they ought not to insist on a standard type of car house. In a recent number of the *Electrical Engineer* of New York, Mr. Alfred E. Braddell, who is connected with the Underwriters' Association of the Middle Department, says:—"It has been, I think, fully demonstrated that the great difficulty at the time of fire is the inability to remove the cars from the building, so that in many cases they have been entirely destroyed. To get over this difficulty it has been suggested to specify that the tracks be constructed on a gradient falling toward the entrance. If such is decided on the next question is what percentage of grade should be specified. . . . A number of well-known electrical engineers and railroad operators have been approached on this matter, with not very satisfactory results. The engineers suggest not less than a 3 per cent. grade, but this is objected to by the operators for many reasons, stating that the brakes would have to be continually applied, which they claim would cause their deterioration; also that with such a grade the cars could not be kept under proper control, being liable to move unexpectedly, perhaps injuring life and resulting in a suit for damages. Where, then, are we to strike the happy medium? The vital point is to have some method for rapidly removing the cars from the burning building, and the only feasible manner of accomplishing this appears to be a *safe* and *legitimate* grade. . . . On account of the enormous amount of capital being invested in electric railroads, I am sure this point is worthy of the utmost consideration. The subject is one peculiarly to be helped by discussion, as it is a new question in a new field, with little to be learned from horse railway precedents."

Birmingham.—At Tuesday's meeting of the Town Council the Mayor moved that the notice of the Birmingham Electric Supply Company to apply for a Provisional Order extending their area of supply should be referred to the General Purposes Committee. It appeared to the Committee, he said, that there were two grounds which might justify the Council seeking for powers themselves. The first ground was a reasonable anticipation that the profits to be derived would be large, and the second was that it was necessary in order to safeguard the interests of the consumers and the public generally. Putting together all the statistics that had been obtained, the General Purposes Committee had come to the conclusion that both in the case of companies and corporations the profits at present were inconsiderable, and there was no indication that they were likely to be very large. With regard to the second point the Corporation had power to apply to the Board of Trade to revise the prices charged every seven years. Besides this, there was no monopoly. On the whole the Committee came to the conclusion that it would be better, for the present at least, that they should not become suppliers of the electric light and power themselves. Alderman Johnson said a great many mistakes had been made through false analogies. There was no real analogy between the gas or water and the electric light. It was not like the water, a necessity of life; and it was not like the two gas undertakings, practically a monopoly. He was quite sure, as a matter of policy, it would be well for the Council to wait until a future time, when they would be able to acquire the undertaking, not at an extravagant premium, as in the case of the gas and water, but at the commercial value of the concern at the moment. The Mayor, in conclusion, said that the General Purposes Committee approached this question with a strong feeling in favour of the Corporation taking up the electric light, and it was only when they probed the matter to the bottom that they came to a contrary conclusion. The resolution was carried with one dissentient.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 226.*)

The Conductor in Practice—Aërial Lines.

Proceeding to practical requirements, the first consideration is the metal for the conductor. In selecting this, the desideratum is all-round cost—*i.e.*, which metal will be the cheapest, taking into account the predetermined heat waste and conditions of erection and insulation. To guide the choice it is necessary, first of all, to know the specific resistance of the metals usually sold in the form of solid or stranded wire. Copper, or its alloys, and iron and steel are practically the only materials available for the purpose.

The resistance to the passage of an electric current in a wire of unit length and of unit area of cross section is defined as the specific resistance of the substance. The quantity thus designated gives a ready means of comparing the relative *electrical* suitability of the different metals.

Table E.

Metal.	Sp. resistance in microhms.	Specific gravity.	Breaking strain in lbs. per sq. inch.	Price per lb. in pence.
Copper annealed	1·615	8·8	—	8·5
Copper hard-drawn ..	1·642	8·9	56,000	8·5
Bronze (tin and copper)	4·42		84,000	10·0
Silicium bronze	1·7	8·4 to 8·7	90,000	
Phosphor bronze.....	3·0 to 60		—	12·0
Aluminium bronze.....		—	—	
Iron, ordinary, soft —	9·827		47,000 to	
Iron, galvanised, killed.	10·0 to 11·0	7·6 to 7·8	85,000	1·0
Steel, ordinary, soft ...	14·5 to 15·0	7·8 to 7·9	135,000	1·5
Steel pianoforte wire...	16·0 to 16·5	7·75	335,000	2·0
Manganese steel	73·0	7·8	110,000	3·0

The above figures are necessarily only approximate. The specific resistance determinations have been made at 32° F.

In Table E are arranged the copper alloys and various other metals in the order of their specific resistances; the specific gravity, breaking strain in lbs. per square inch, and the approximate price per lb. of the several metals are also given for rough comparison. It will be seen that iron has nearly seven times the specific resistance of copper, and so for a given resistance of line, the area of an iron wire will have to be, say, seven times that of a copper one. The specific weights are in the ratio of 8·9 : 7·8, and the weight of the iron line, relative to that of the copper line, will be expressed by

$$7\ W\ \frac{7{\cdot}8}{8{\cdot}9},\ \text{or}\ 6{\cdot}18\ W,$$

where W is the weight of the copper in lbs. And the costs will be respectively 8·5 W for the copper, and 6·18 W × 1 for the iron. A bare copper line will, therefore, cost about 27 per cent. more than an electrically-equivalent iron wire. From the simple consideration of first cost of conductor, then, it appears that iron is superior to copper. In relation to the total line cost, however, the reverse of this is the case. For the weight and breaking strain have to be taken into consideration. The breaking strain of hard-drawn copper of 98 per cent. conductivity is about 56,000lb. per square inch; whereas that of well-killed galvanised iron is about 85,000lb., so the spans may be made longer with iron wire in the proportion of 85 to 56; or, say, 50 per cent. Yet, since the iron wire is 6·18 times as heavy as the copper, the supporting devices must be correspondingly stronger. The figure of merit of a metal *per se* may be expressed as the product of the reciprocals of the specific resistance, the specific weight and price multiplied by the breaking strain—the best metal giving the largest figure of merit. Thus, for copper

$$\frac{1}{\text{Sp. R}} \times \frac{1}{\text{Sp. W}} \times \frac{1}{\text{Price}} \times \text{breaking strain}$$

$$= \frac{1}{1{\cdot}642} \times \frac{1}{8{\cdot}9} \times \frac{1}{8{\cdot}5} \times 56{,}000 = 450.$$

$$\text{For iron } \frac{1}{10{\cdot}5} \times \frac{1}{7{\cdot}8} \times \frac{1}{1} \times 85{,}000 = 1{,}040.$$

* All rights of reproduction reserved.

From these general considerations, galvanised iron appears to be, roughly, about twice as well adapted for overhead lines as hard-drawn copper. But this proportion is not maintained when all the conditions of the problem are taken into consideration. In the first place, the greater bulk of the iron is objectionable on account of the expensive posts and attachments necessary to carry the weight; and secondly, iron, although galvanised, rusts, and has a shorter life than copper; and so the cost of maintenance is far greater than with copper or its alloys. Again, old iron wire has practically no marketable value, whereas copper is always saleable. As regards total prime cost of line it is not easy to say which metal is the cheaper for all cases, but generally for light work, such as telegraph and telephone lines, there is very little to choose between the two. With heavy power lines, however, copper will always work out the cheaper (unless the relative costs be very different from those assumed here), and the weight of the iron becomes practically prohibitive. And even with large copper cables of, say, 19 strands each of No. 16 S.W.G. (and larger) the supports have to be so frequent as to form a very important item in the cost of the *whole line*. In such cases it is usual to suspend the copper conductor from a small steel wire carried on insulators; by this means the spans can be materially lengthened, and the total cost largely decreased.

If, however, the conductor is insulated, copper is by far the cheaper metal, since the necessary bulk of insulation material is much less. The areas of the two metals are for equal resistance as 1 : 7, say, and the diameters will be as $\sqrt{1} : \sqrt{7}$, or $1 : 2{\cdot}63$; and for an equal thickness, t, of insulation, the volume of insulation material will be as $(1 + 2\,t)^2 - 1^2 : (2{\cdot}63 + 2\,t)^2 - 2{\cdot}63^2$. But since to maintain the insulation resistance constant per unit length of conductor it is necessary that the depth of the dielectric vary as the diameter of the conductor, the diameter of the iron wire over the insulation will have to be $2{\cdot}63 + 2\,t\,\frac{2{\cdot}63}{1} = 2{\cdot}63 + 5{\cdot}26\,t$. To illustrate the meaning of these ratios let the copper conductor be No. 10 S.W.G., and let $t = 0{\cdot}1$ inches. Then, the diameter of copper conductor = 0·128in., and the diameter over the insulation = 0·328in. The diameter of iron conductor = 0·336in., and the diameter over the insulation = 0·862in. Now the insulating materials generally used, such as pure rubber, vulcanised rubber, &c., are costly, and therefore the iron conductor is commercially impossible.

These comparisons have been made between iron and copper, because they are the metals most likely to be used for power circuits. The copper alloys, however, present many advantages and combine the high conductivity of copper with the tensile strength of the best iron. Bronze wires are in general use for telephones and telegraphs and will inevitably come into favour for transmitting power. Silicium bronze has a conductivity nearly as high as that of hard-drawn copper and a breaking strain of at least 90,000lb. to the square inch. Bearing in mind the relative weights for a given resistance, it is evident that the spans can be made longer with the bronze than with galvanised iron; in practice, it is found that they may be made about 50 per cent. longer, and less bulky and costly insulators are necessary. One reason why the copper alloys have not been used much as yet is a real or fancied difficulty in procuring a wire of a specified resistance and tensile strength, it being found that one of these qualities is frequently gained at the expense of the other. This difficulty is merely a detail of manufacture and will soon be overcome if it is not already so. The cost, about one shilling per lb., is high, but will be reduced as the demand for the alloys increases.

The figure of merit of silicium bronze as previously estimated for hard-drawn copper and iron is $\frac{1}{1{\cdot}7} \times \frac{1}{8{\cdot}7} \times \frac{1}{12} \times 90{,}000 = 508$.

It is better than copper by about 12 per cent. It should be noticed that the atmosphere has practically no effect upon most of the copper alloys, and that they are not so liable to crystallisation as hard-drawn copper. These qualities largely reduce the cost of line maintenance, and in conjunction with the other points already discussed render silicium bronze perhaps the best all-round metal for power lines.

Underground Lines, Conduits, &c.

It is becoming generally recognised that aërial lines, whether of bare copper or insulated cable, though permissible in open country where they are free from wilful or accidental damage, are a source of possible danger in towns, &c. And it is also apparent that such lines are especially subject to interference from lightning. (The æsthetic view of the question is irrelevant to the purely engineering aspect, and need not be discussed.) It is evident, however, that if a line has to be made permanent, and be required to work continuously at a minimum cost of maintenance and depreciation, it must be protected from atmospheric influences and accidental injury. These ends are best attained by laying the cables in the earth. Experience gained with gas and water mains at once points to two methods: in one the cables are simply *buried in the soil* at a safe depth; in the other, they are *run in conduits or pipes.*

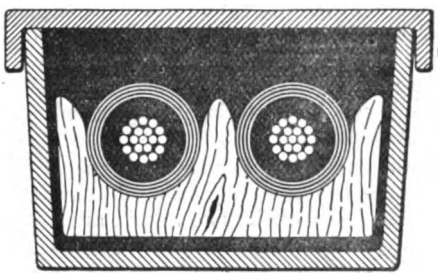

FIG 19.—Callender Solid Bitumen System. Cross Section of Trough.

If the first system be adopted, it is evident that the insulation of the cable must be protected from mechanical injury during laying, and afterwards from a possible erosive action of the soil, and, perhaps, from the effects of water. This suggests the use of a metallic sheathing of lead if the Water Company's practice be followed, or iron if the Gas Company's experience be accepted. Both kinds of armouring have been used with success here and failure there. The causes determining the result are often obscure, but electrolytic decomposition, assisted more or less by the peculiar constituents of the soil and water, can always be shown to have taken place. In fact, the problem is complicated by the inevitable leakage of at least one main, usually the negative, and sometimes by weak points on both of them. The passage of an electric current through water breaks up the chemical combination into its component gases, oxygen and hydrogen. The nascent oxygen immediately attacks any

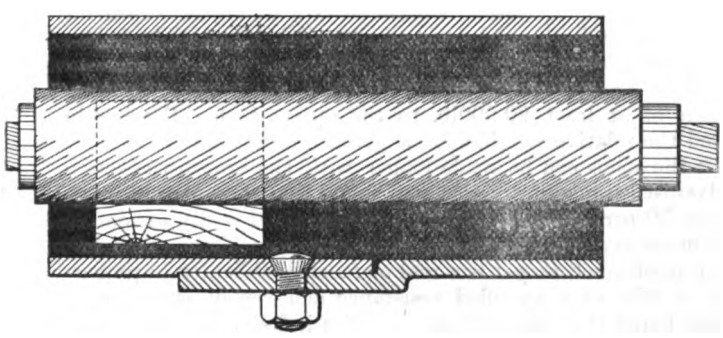

FIG. 20.—Callender Solid Bitumen System. Sectional Elevation of Trough.

oxydisable material in contact with it—the lead sheathing, for example—and soon changes its nature. Other more obscure chemical changes, resulting in the formation of free chlorine, hydrochloric, and sulphuric acids, and other corrosive agents, may also occur if the soil be impregnated with suitable salts. Hence, wherever there is a leakage of electricity, there is a tendency to destroy the metallic sheathing, the insulation, and, finally, the copper conductor itself. It is, therefore, necessary to protect the metallic armouring by servings of jute soaked in tar, ozokerite, or some preservative compound. And in all cases it is wise to lay the cables in fresh soil, clay, or fresh water gravel, and to protect them by boards from mechanical injury, such as an inadvertent blow from a pickaxe. The armoured concentric mains laid at Bradford for the lighting service are a good example of this class of work. They have been in continual use for about four years, and the author is assured by the engineer that the insulation resistance has increased since they were laid in the ground, and that no trouble is experienced with the coupling-up of consumers through the iron junction boxes already referred to.

The second method may be considered under two heads:—(*a*) the "built-in" systems, in which the cables, usually strips of bare copper, are laid in conduits, and covered-in permanently, so that they cannot be reached without taking up the top soil; and (*b*) the "drawing-in" systems, in which continuous lines of waterproof conduits or pipes or troughing are laid, with drawing-in boxes at intervals of from 80 to 100 yards in the straight, and at all sharp bends.

A complete discussion of these systems of laying cables is not necessary here, since they properly belong to a treatise on central station for distributing light (and perhaps power) over a large area to a number of points in close contiguity; whereas this book treats, primarily, of the transmission of power between places relatively far apart, and, secondarily, of its distribution

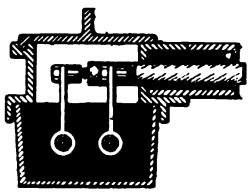

FIG. 21.—Callender Solid Bitumen System. Cross Section of Service Box.

to a comparatively few points in a limited area. And should it be deemed advisable to run the cables underground, some modification of the first method (cables simply buried) is sure to be selected from the mere consideration of first cost. If, however, the cables are likely to be frequently disturbed for coupling-up supply mains to new points, or if they are likely to be increased in number within a reasonable time from the first installation, then one of the second systems may prove to be the cheaper in the long run, but this contingency is improbable on the supposition laid down in the preface and introduction. It will be, therefore, sufficient to illustrate the methods by a few characteristic drawings.

(*a*) One of the best "built-in" systems is the Callender Solid Bitumen system (illustrated in Figs. 19 and 20). The troughs are made in cast iron, in lengths of 6ft. with sockets at one end, so that when fitted together there is a free "run" inside. The lengths are coupled together by counter-sunk bolts and

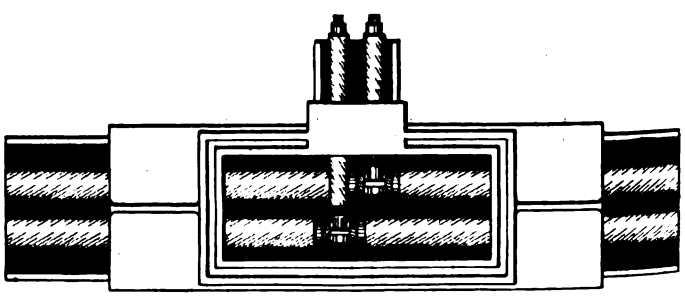

FIG. 22.—Callender Solid Bitumen System. Plan of Service Box.

nuts. Bends and circular pieces are used to carry the mains round corners and for changing the levels at crossings, but considerable deviation from the straight line is possible with the standard type. The method of laying is as follows:—The troughs are first connected in position and then a small quantity of molten bitumen is run in and before it sets bridges of bitumenised wood are placed in it at intervals of 18in. The insulated cables are next laid in position and held in place by these bridges so as to be clear of the sides and bottom of the trough and of each other. The interior space is then carefully filled up with bitumen to within half an inch of the top, and the whole is finished off by a covering of Portland cement or cast iron lids. It is obvious that cables laid in this manner are completely protected from the action of damp, water, or

Digitized by Google

gases, and repairs can be easily and rapidly made. The method of coupling up the service mains is illustrated in Figs. 21 and 22.

(*b*) The drawing-in systems are illustrated by Figs. 23, which refers to the Callender-Webber systems and shows the conduit, a brick pit and method of coupling the feeders or service mains without junction boxes. The conduits consists of

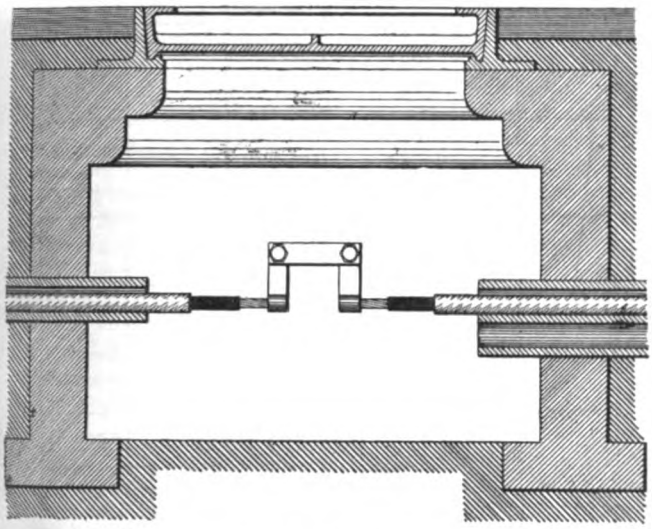

Fig. 23.—Callender-Webber Drawing-in System. Section of Manhole.

bitumen concrete formed in blocks 6ft. in length and pierced by "ways" (*see* Fig. 24). The standard sizes of these cases are for 2, 3, 4, and 6 ways of either 1½in., 2in., 2⅜in. or 3in. in diameter. To join the lengths, the cases are brought together and an iron mandril placed in each of the ways. Melted bituminous concrete is then run between the two cases and rammed home. When the bitumen is cool the mandrils are withdrawn leaving

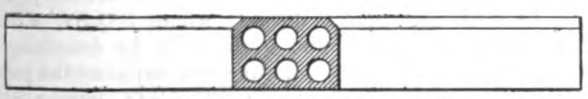

Fig. 24.—Callender-Webber Conduit.

a perfect joint as strong as the main case itself, The "ways" are quite smooth throughout their entire length, but it sometimes happens that the cables sink into the bitumen in course of time and, therefore, cannot be withdrawn. The Callender-Raworth system (Fig. 25) is designed to obviate this difficulty and combines the mechanical strength of the solid bitumen system with the facilities of a drawing-in system. It consists of cast iron troughs with flanges. The spaced wooden bridges

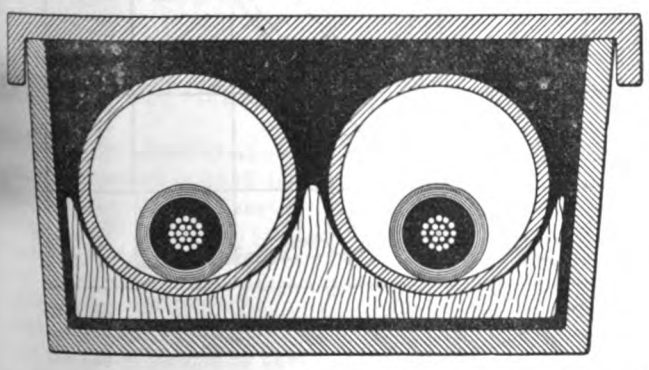

Fig. 25.—Callender-Raworth Drawing-in System. Cross Section of Trough.

are fixed at short intervals, and on these are laid tubes of specially made paper impregnated with bitumen. The tubes are joined together by sleeve pieces and are then buried in solid bitumen. The conduit is closed on the top by a cast iron lid with flanges fitting over the sides of the trough. The lighting mains now being laid at Huddersfield are on this principle.

(To be continued.)

INDUCTIVE CIRCUITS.

BY W. E. SUMPNER, D.SC.

Although much has been written concerning the action of combinations of coils and condensers when used with alternating currents, the quantities, such as self-induction, capacity, &c., which determine the behaviour of these conductors, have only been referred to in a general way, and their relative values for such cases as are liable to occur in practice have, as far as I am aware, never been actually indicated. The usual thing has been to choose values for these quantities, to work out the results numerically, and to assume that the curves representing these special cases give a correct idea of the effects which actually occur. The values chosen, however, have, as a rule, been such as could obtain only in very exceptional circumstances; and it may, therefore, be of some interest to reproduce here some curves, which I drew out for myself two or three years ago, and which serve to show how the effects vary with different relative values of the inductance, capacity, resistance, &c., of the various parts of the circuit.

Considering first the case of a coil and condenser in series, subjected to an alternating pressure of V volts, it has been frequently shown that the current A in amperes is related to V by the equation

$$A = \frac{V}{\sqrt{R^2 + \left(Lp - \frac{1}{Kp}\right)^2}} \quad . \quad . \quad . \quad (1)$$

where R is the resistance of the coil in ohms, L its self-induction in secohms, K the capacity of the condenser in farads, and where p is the quantity

$$p = 2\pi n$$

in which n is the frequency of the current in periods per second.

The quantities Lp and $1/Kp$ are each measurable in ohms, the former being called the "inductance" of the coil, and the latter the "inductance" of the condenser. It follows from equation (1) that the voltage required to produce a given current A amperes is proportional to

$$\sqrt{R^2 + \left(Lp - \frac{1}{Kp}\right)^2}$$

or to the hypothenuse of a right-angled triangle, one of whose sides represents R, and the other the inductance $Lp - 1/Kp$. If, therefore, in Fig. 1, we set off a vertical distance O A equal to R, and a horizontal distance O L equal to $Lp - 1/Kp$, the length L A will represent the voltage needed to produce the given current; and thus, if we set off an ordinate L a at L equal to L A, and repeat this operation for different positions of the point L along the horizontal axis, we get a curve A a, the ordinate of which represents the voltage needed to produce the given current, while the abscissa, reckoned from the point O, represents the value of the inductance $Lp - 1/Kp$. The curve A a thus shows the effect of varying the self-induction of the coil, if the capacity of the condenser and the frequency of the current remain constant. If O K is equal to $1/Kp$, the inductance of the condenser, and if K L is equal to Lp, the inductance of the coil, then O L is equal to $Lp - 1/Kp$, and the voltage needed to make a current A amperes flow through the coil is L a. If K L is greater than K O this voltage gradually diminishes as the self-induction is decreased until $Lp = 1/Kp$, when the voltage is equal to O A. As the self-induction is further diminished the voltage increases, and continues to increase till L is nothing, in which case the ordinate at the point K represents the voltage. Five curves have been drawn in Fig. 1 corresponding with various values of the resistance R. These curves are A a, B *b*, C *c*, D *d*, and E *e*. The method of construction is in all cases the same, and is sufficiently indicated by the equations L A = L a, L B = L *b*, &c., and L E = L *e*. In Fig. 1 the distance O K, representing the inductance of the condenser, is supposed to be 20 ohms. This means that if 100 volts are applied to the condenser terminals a current of 5 amperes will pass through the condenser. The resistance of the conductor is supposed to be 2 ohms for the curve A a, 5 ohms for B *b*. 10 ohms for C *c*, 20 ohms for D *d*, and 30 ohms for E *e*,

Digitized by Google

In order to judge which of these curves most nearly represents a usual state of things, it is instructive to compare the ratio of O K to the lengths O A, O B, &c. The length O K is the inductance of the condenser; but it is also the value of Lp, the inductance of the coil, for which the voltage needed to produce a given current is a minimum. But if R is the resistance of the coil, the ratio of Lp to R is the tangent of the angle of lag of the current in the coil behind the voltage at its terminals, and this ratio is never large. Indeed it is exceptional to have Lp as large as R. With ordinary transformers, even when the secondaries are open-circuited, the value of Lp is rarely greater than R, while if the secondary is closed it is much less. With alternating current motors the ratio may sometimes be greater than unity when the load is light; and with choking coils the ratio is sometimes considerably greater. Circumstances must, however, be exceptional, if this ratio is greater than two, although a case in which the ratio is 5 sometimes occurs, and even ratios of from 10 to 15 are possible with alternating currents of ordinary frequencies. The latter cases occur with conductors having very small power factors, such as a hedgehog transformer when on open circuit. Probably the most striking case of this kind happens when one alternator drives another as a synchronous motor, the electromotive forces of the machines being very different from one another. But this is a case of such little practical interest that it need not be considered. We conclude, therefore, that the

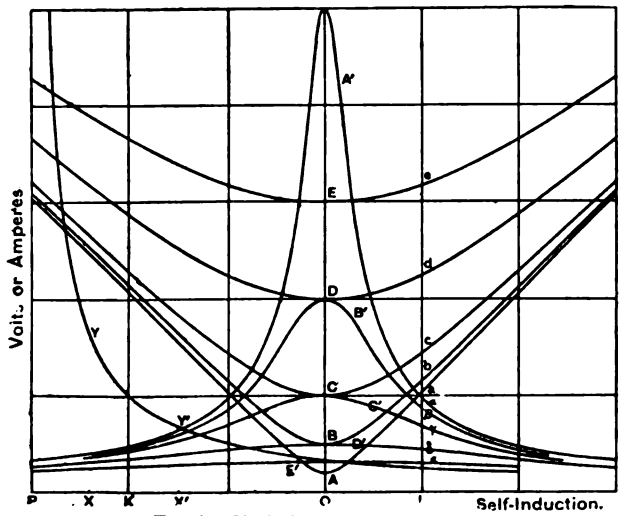

FIG. 1.—Variation of Self-Induction.

curves in Fig. 1, which represent conditions easily realisable in practice are those for which Lp/R is less than 2. Now this ratio is the ratio of O K to the ordinate of the curve at O. This ratio is 10 for curve A a, 5 for curve B b, 2 for curve C c, 1 for curve D d, and 0·66 for curve E e. The two latter curves are thus the ones which can be easiest produced experimentally, while the three former represent more or less unusual cases.

It is instructive to compare with these curves, the ordinates of which represent the voltage needed to produce a given current, a corresponding set of curves representing the current produced by the application of a given voltage to the circuit. If we draw a rectangular hyperbola Y Y′ (such that the product of ordinate and abscissa is constant all along the curve, thus P X. X Y = P X′. X′ Y′) we can easily get the second set of curves from the first. Take any ordinate, say L c, of one of the curves. Project c horizontally on to the curve Y Y′, and the abscissa of this point on Y Y′ is the ordinate, L γ, of the new curve. In this way the curve A′ α is got from A a, B′ β from B b, C′ γ from C c, D′ δ from D d, and E′ ϵ from E e. As before, the curves E′ ϵ, D′ δ represent usual cases, while C′ γ, B′ β, and A′ α represent exceptional ones. It will be noticed, therefore, that although the current rises to a maximum and then diminishes as the self-induction of the coil is continuously increased, the proportional rise is not so very large under conditions such as are likely to occur. The ratio of the maximum current to the current when the self-induction is *nil* is 10·5 for A′ α, 4·3 for B′ β, 2·3 for C′ γ, 1·43 for D′ δ, and 1·22 for E′ ϵ.

The effects produced by altering the capacity of the condenser, or the frequency of the current, can be traced out in a similar manner, and the results obtained are exhibited in Figs. 2 and 3.

In Fig. 2 the lengths O A, O B, &c., represent the resistances taken for the coil. The length S O represents to the same scale the quantity Lp, now to be considered constant. The

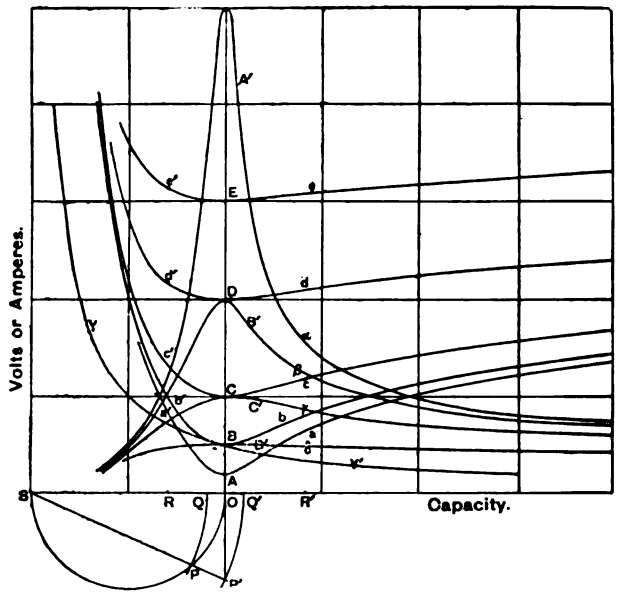

FIG. 2.—Variation of Capacity.

capacity of the condenser is represented by the horizontal distance measured from S, such as S Q′, the scale for capacity being so chosen that when $K L p^2 = 1$ the length S O represents the corresponding value of K. Then for any value, S Q′ for the capacity K, the inductance $1/Kp$ must be inversely proportional to S Q′ and must be S Q where S Q. S Q′ = S O². The point Q can easily be found graphically by describing a semi-circle on S O as diameter, finding by compasses the point P′ on the vertical from O, for which S P′ = S Q′, joining S P′, cutting the circle in P, and finding Q such that S P = S Q.

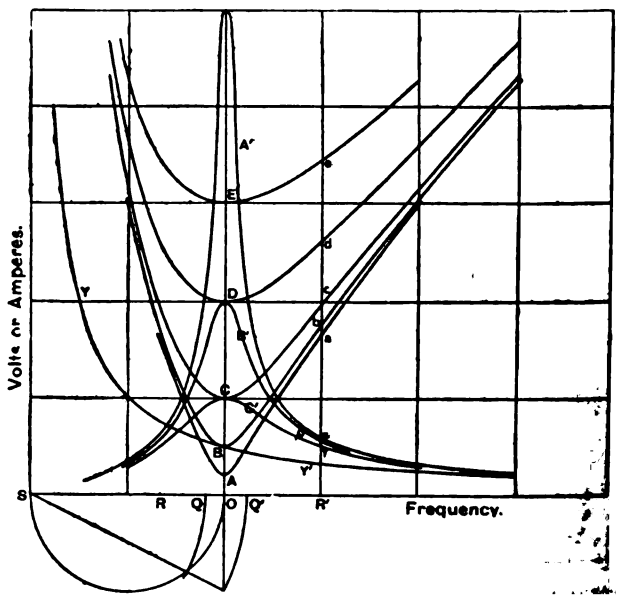

FIG. 3.—Variation of Frequency.

Similarly, the point R corresponding with any values S R′ of the capacity can be easily found. Now S O is the inductance of the coil, or Lp, while S R is the inductance, $1/Kp$, of the condenser when the capacity is represented by S R′. So that R O is equal to the difference $Lp - 1/Kp$ of the two inductances. It follows that if O A is the resistance of the coil, the length R A represents the voltage needed to make a given current

Digitized by Google

flow through the conductors when the capacity is equal to S R', at R' therefore set off an ordinate S a equal in length to R A. Similarly at R set off an ordinate R a' equal to S R, for this can be shown to be the voltage needed to produce the current when the capacity is equal to S R. In this way the curves a' A a, b'B b, c'C c, d'D d, e'E e, can be all drawn; and the corresponding curves denoting the currents produced in the circuit by the application of a constant voltage can be deduced by the same process as in Fig. 1. The lengths O A, O B, &c., denoting the resistances in these curves are the same as those in Fig. 1, and the inductance S O in Fig. 2 is the same as O K in Fig. 1, so that the same remarks apply to the curves in Fig. 2 as were made above with reference to the curves denoted by the same letters in Fig. 1.

In Fig. 3, which exhibits the effect of varying the period, the frequency is plotted to such a scale that, when the current frequency is such that $K L p^2 = 1$, the length S O represents this particular frequency, and also the value of $L p$ at this frequency. The lengths O A, O B, &c., representing the resistance of the coil, are plotted to the same scale of resistance as the inductance $L p$. As before, find a series of points Q Q', R R', &c., such that $S Q . S Q' = S R . S R' = S O^2$. Then, when the frequency is represented by S Q', the inductance of the coil $L p$ will also be represented by S Q', while the inductance $1/K p$ of the condenser will be denoted by S Q. The length Q Q' will represent $L p - 1/K p$ the inductance of the circuit, and the voltage necessary to send a given current will be represented by the hypothenuse of a right-angled triangle, one of whose sides is Q Q' and the other is O A for the curve A a, O B for the curve B b, &c., &c. The way to draw the curves A a, B b, &c., is thus pretty obvious, and the reciprocal curves showing the current produced by a given voltage can be obtained as in the other cases. It will be noticed in all these curves, shown in Figs. 1, 2, and 3, that the current changes very rapidly in the neighbourhood of the line O E for the curves A'α and B'β, even for the slightest alteration of the variable denoted by the abscissa of the curve (self-induction capacity or frequency, according to the case considered), but this is not the case at all with the curves C'γ, D'δ, or E'ϵ, which alone represent circumstances such as may easily arise.

We have only considered the case of a coil and condenser when connected in series. It is obvious that when the coil and condenser are put in parallel the results will be similar. As a matter of fact, the curves shown in the diagrams will represent *exactly* what takes place, only the curves A'α, B'β, C'γ, D'δ, E'ϵ, instead of denoting the current produced by a given voltage, will now represent the voltage needed for a given current in the main circuit, while the curves A a, B b, C c, D d, E e, will represent the current produced by applying a given voltage. The lengths O A, O B, &c., which formerly denoted the resistance of the coil, will now denote the reciprocal of that quantity.

THE ELECTRIC LIGHTING OF BRUNN THEATRE.

One of the oldest Continental electric light plants is that which was started in 1882 by the Société Electrique Edison de Paris, at the Brünn Theatre. After a run of eleven years, during which the old-type machinery seems to have done remarkably well and to have suffered little depreciation, this plant is now about to be taken over by the municipality. This theatre claims the distinction of never having had a single gas jet burning within its walls; and is probably one of the first—if not the first—theatre to have been electrically lit, so that a few details of the plant which have been sent us by Mr. Francis Jehl, who superintended its erection, may prove of interest to our readers.

The dynamos are of the old Edison "K" type, having three parallel magnets, each machine giving an output of 20 kilowatts. There are four of these machines, and only one of them has an entirely different commutator from that with which it started life. The other commutators have held out through no less than 3,300 performances; and only once during this time has an electrical breakdown occurred. This isolated failure of the plant was, moreover, due to the bursting of a water-pipe. It may be mentioned that the Edison Company had contracted to supply the light, subject to a fine of 300fl. for each breakdown. The steam engine is capable of developing 110 H.P., and is of the twin-cylinder non-condensing type. It is supplied with steam from three Dupuis boilers.

The theatre contains 1,446 16 c.p. glow lamps, 5 regulating arc lamps, and 1 hand-fed arc lamp. Besides these, there are various other lamps for stage effects and a 4 H.P. electromotor. The average daily consumption is about 46·5 kilowatts during the time of the performance, which amounts to about 100,800 E.H.P. hours per annum. During 1892 the total cost of production, including salaries, wages, &c., amounted to £964, or about 104 E.H.P. hours per £1, or 2½d. per E.H.P. hour.

TRAMWAY MOTORS.*

One of the points to be considered in connection with tramway motors is a compact design adapted for the limited space under the floor of the car. With wheels of about 30in. diameter, and the condition that the lowest point of the mechanism must clear the ground by at least 3in., this is a difficult problem. All parts must be easily accessible and capable of being exchanged, whilst small weight and large power are essential. The author illustrates six different types of motors and gear made by the Edison Company, the Thomson-Houston Company, the Short Electrical Railway Company, and the Oerlikon Works. The power of these motors, as stated in a table, varies from 12 to 17 H.P., and the weight from it is 0·75 to 0·9 of a ton. The general practice at present is to have simple reduction gear 1 to 4 or 1 to 5, and an armature speed of 400 or 500 revolutions per minute, and two motors per car, one on each axle. The loss of power in the gear is from 4 to 6 per cent. The author does not advocate gearless motors. Reckenzaun's worm gearing is stated to be as efficient as double-reduction gear. The following table gives the efficiency at full load for different methods of gearing:—

Gearing.	Armature speed.	Efficiency, per cent.	
		Total.	Motor only.
Double-reduction	1,100	60—65	75—85
Worm and wheel	1,200	65—68	75—85
Single-reduction	450	80—83	85—88
Gearless	110	82—85	82—85

The motors are series-wound, and may be coupled in series or in parallel. With the former arrangement the total E.M.F. (usually 500 volts) is divided between the two motors, but in case of one pair of wheels skidding the available power is reduced in both motors.

With the parallel arrangement this defect is absent, but to get the power evenly divided between the two motors the current must be split, not through the armatures only, but also through the field, which necessitates the employment of two reversing switches. A very important point is the regulation of speed and power for which two methods are available: (*a*) by resistances in the main circuit, and (*b*) by sub-dividing of field coils. The first method is the simpler, but the construction of the rheostats presents considerable difficulties, owing to the limited space within which they must be housed. There is also waste of power, which is avoided under the second method, but the latter necessitates the employment of a very complicated switch and connections. The author recommends the employment of an ironclad type of field to avoid magnetic leakage, and give mechanical protection to the armature. There is with external poles the danger that pieces of iron lying on the roadway may be picked up and get into the armature. Whether the field should be bipolar or multipolar is still an open question.

Handbook for Engineering Visitors to America.—The "Committee on Information and Courtesy" of the American Society of Civil Engineers have prepared a neat handbook for the information of foreign engineering visitors during the Exhibition. It contains a map of the United States and list of public works, railroads, mines, and manufacturing establishments, which might be of interest to visitors.

GRAVITY AND THE ETHER.

The attitude of awe with which we have hitherto regarded the ether is intensified by the further proposition as to its complicated simplicity, so to speak, which is made in a letter by Prof. LODGE this week. The latest property with which this well-burdened medium is to be invested is really a *pair* of properties: a pair, so nicely balanced, so delicately opposed, that the effect of the one is completely annihilated by the effect of the other. One thing is certain, that the existence of two such mutually cancelling effects can never be proved, disproved, or even detected; for we can only know of anything in so far as we can perceive it, and we can only perceive it in so far as it is allowed to do something. Permanent equilibrium implies eternal unknowableness. Electrical theory has been making no less rapid strides than electrical practice, and the day is surely approaching when we shall be able, if not to answer the question, "What is electricity?" at all events to give as rational an answer as can to-day be given to the question, "What is sound?" Little more is to be expected from purely electrical research unless by revealing something of the nature of ether. Every step towards our knowledge of this medium is of the greatest interest to the student of electricity, and even if the consideration of Dr. LODGE's suggestion leads us wide of electrical science, we pursue it in the hope that it may guide us to an intelligible theory.

One of the properties assumed by Dr. LODGE is the viscous retardation of matter moving through the ether; the other is the finite rate of propagation of gravitational stress through the same medium. The one of these exerts a retarding force on a moving planet, the other an accelerating force; and it is assumed that the conditions are always and everywhere such that the algebraic sum of their moments around the centre of the system shall be constantly equal to zero. The requirements are nothing short of stupendous; and our admiration of the ether must go up by leaps and bounds as we learn more and more of its resourcefulness. But—and this is an important element of doubt—we are not quite satisfied that

Digitized by Google

any consistent mathematical theory can be based upon the hypothesis. We must, of course, assume that the law of aberration and the law of retardation due to viscosity are invariable in every part of a moving material system; the same, say, at the orbit of Neptune as at the orbit of Mercury. Yet, if we make these necessary assumptions, we find it very difficult to determine the law of variation of the two effects with change of velocity and radius vector. How, for example, shall we reconcile the proposed explanation with Bode's law? Prof. Lodge proposes that the viscous force shall be directly proportional to the velocity of the planet through the ether. The moment of this force would, therefore, on an average, be equal to the product of the mean velocity into the mean radius. But the moment of the accelerating force due to gravitational aberration would vary in another manner, namely, with the product of the mass of the planet into the mass of the central attracting body and the velocity of revolution of the one round the other. It, therefore, the two moments are to cancel out in every case, it can only be by giving to a system of planets a set of periodicities which shall bear quite a different relation to their distances from the centre to that settled by what is generally known as Bode's law. Again, it is difficult to see how there could be equilibrium of the two moments both at the perihelion of the planet, when it is beginning to be retarded by gravity, and at the aphelion, when it is beginning to be positively accelerated. Lastly, since it is evident that the rotation of all the planets must exert an aberration moment on the sun, while it is quite inconceivable on any hypothesis that this is balanced by the solar friction against the ether, it is a matter for surprise that not the slightest elliptic movement or degree of wobbling is apparent in the sun's motion. After so many millions of years one would expect to find some evidence of this continuous want of equilibrium. In fact, while we should like very much indeed for the ether to have these remarkably antagonistic properties, we are not quite prepared to see that it really can have them.

Apart altogether from the direct consequences of attributing viscosity and an aberration of 20sec. to the ether which transmits gravity, and making this ether identical with that which transmits light, we must not lose sight of the many other duties which are imposed upon this ether, nor of the necessity for introducing some sort of harmony among the properties with which it is to be endowed. The earliest of the duties imposed on the ether, and the one which led to the suspicion of the existence of this substance, was that of conveying light waves. Since then it has had to undertake many an additional arduous duty. Matter of all kinds has been conceived to be nothing but a collection of complicated and highly-differentiated ether vortices, and all the properties which matter possesses have been attributed to the various interactions of those same vortices. The electric current, if not considered to be one and the same thing as ether, is assumed to be so closely associated with ether that the distinction becomes almost metaphysically fine. Electric charges and ether stresses have long been shown to be identical. Magnetism, on every rational hypothesis which has yet been put forward, implies a modification of the ether in and around the magnetised body. And the phenomenon of electromagnetic induction, as well as of ordinary magnetic induction across any intervening space, is explained on the assumption of the setting up of disturbances in the ether in that space, disturbances which continue to be emitted as long as any change continues in the state of the inducing body. In fact, all the phenomena of electrostatics and electromagnetics, of matter and of force, have, with the two exceptions of gravitation and the mysterious function called life, been directly referred to the properties of one and the same ether for their ultimate explanation. And, now it is shown that there is no inherent objection to the ether being burdened with gravitation also; it has been shown by Mr. Oliver Heaviside that gravity may be explained by means of waves propagated in an elastic ether, and by Prof. Lodge that this ether need not be any different from the ether which does all the rest of the work. But the suggestion is made only at the expense of some properties which hitherto the ether has been asserted to possess, notably, its perfect elasticity. If we impart to the ether such a degree of viscosity as will altogether swamp out the aberration at the speed of the earth, we have to account for a very considerable absorption of the rotational energy of the sun into the ether itself. We may, of course, accept the hypothesis of M. Hirn, that energy dissipated in the ether of remote space is employed in the construction of fresh atoms of matter out of plain ether; and thus account for the energy when it is gone. But there still remains the problem as to the extent to which such a large additional rate of dissipation of solar rotational energy, besides that accounted for by tidal action, must modify our views as to the remote history of the solar system and reduce our calculations as to the age of the sun. The whole question is, in short, extremely complicated, and we cannot see that Dr. Lodge's suggestion makes for simplicity. Nevertheless, we need not despair of reducing this chaotic mass of incompatibilities and incongruities to something like order, even though the knot may require a second Newton to unravel it.

OBITUARY.

SAMUEL EDMUND PHILLIPS.

It is with deep regret that we announce the death, at the age of 45, of Mr. Samuel E. Phillips, of the well-known firm of Messrs. Johnson and Phillips, which took place on the 22nd inst. at his residence at Shooter's Hill, in Kent. As may be known to many of our readers, Mr. Phillips has been in failing health for some years, and has of late taken no active part in the business of the firm.

When a boy, Mr. Phillips was brought into contact with telegraphy, his father being at that time engaged with Dr. Whitehouse in carrying out experimental work in connection with the first Atlantic cable. He subsequently accompanied his father in the first Malta and Alexandria cable expedition, after which he became a member of the staff which Colonel Stewart formed to go out with the Persian Gulf cable, remaining at Bushire as a junior clerk. At the end of three years' service he returned to England, and obtained an appointment on the electrical staff of Messrs. Latimer Clark, Forde, and Co., leaving these gentlemen to become electrician to Mr. W. T. Henley, in whose service he remained for ten years. At Mr. Henley's works he was appointed manager of the cable department, and occasionally he accompanied some of the cable expeditions as the head of the electrical department. As an inventor, Mr. Phillips has given us a fluid insulator, which has been largely adopted in India, Egypt and other countries, and has proved of immense value for overhead lines for telegraphy, electric lighting, and power transmission. In 1875 he joined Mr. W. Claude Johnson in partnership, and a small works was established at Charlton. This formed the nucleus of the present extensive range of factories.

Mr. Phillips took the keenest interest in scientific matters generally, and to his good judgment and sound common sense may be attributed in a great measure the success of his undertakings. His genial manner and generous nature made him a universal favourite, and his loss will be deplored by a very wide circle of friends and acquaintances.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 315.)

The crucibles being placed in position in the furnace, the door is lowered into its position, and cemented round the edge with fire-clay. The pyrometer is then inserted through the hole and is also cemented round where it passes through the door. The fire is then lighted, and by means of the damper is kept very low at first; eight hours at least should be allowed for traversing the range of temperature covered by the pyrometer. The first six or seven hours of this time may be in daylight, but by the time that the highest reading on the pyrometer is reached it should be dark, as the regulation from this point will have to be done by eye. The eye is, of course, much better able to judge of colour (temperature) after dark than in daylight, when, indeed, the first dull red heat could not be distinguished at all. The highest temperature indicated by the pyrometer having been reached, the instrument is withdrawn and the peep-hole stopped with the fire-clay plug. It will be necessary from this time to watch the temperature through this hole, the plug being withdrawn from time to time for the purpose. Another five or six hours should be occupied in bringing the temperature gradually up to a bright red heat, and when this is reached the full power of the furnace may be applied, and three or four hours more will be occupied in bringing the temperature up to a white heat. The temperature which can be attained by a furnace of this kind is so great that the best fire-bricks will begin to run. Having raised the temperature to the highest point, there is probably not much advantage gained in maintaining it for any length of time. The fire may, therefore, be allowed to die out and the furnace cool down. This again must be done gradually, not on account of danger to the filaments, but to the furnace. The furnace-door and the fire-door must be kept closed. Rapid cooling will have a very deleterious effect on the furnace, which will require re-building much sooner than it otherwise would do. Twelve hours at least should be allowed for cooling. The crucibles should not be disturbed until they are cool enough to be taken hold of by the hand. If they are handled while too hot, they are likely to be bumped about and the filaments damaged. The wear and tear on a furnace which is used in this way, alternately heated and cooled, is much greater than that on a furnace, such as a glass furnace, which is kept constantly going at one temperature. If heated and cooled off every two days, it will require re-building probably every six months. When the crucibles are cool they are withdrawn and placed on a truck and wheeled to the room where they are to be unpacked.

Having got the crucibles safely from the furnace to the bench where they are to be unpacked, the first thing to be done is to remove the lids. This can usually be accomplished without difficulty, though it is sometimes necessary to use a good deal of force, owing to the lid having become fused in places to the crucible. Care must be taken that the crucible is not knocked or jolted about. The lid being off, it will first be noticed that the powdered carbon considerably has sunk, the space between the carbon box and the crucible being no longer full as it was when the lid was put on. This subsidence is due to the air which was originally imprisoned by the carbon having been driven out and not to any loss of the carbon by burning or otherwise. If through insufficient luting of the lid some of the carbon powder has been burnt, it will be at once apparent by a brown or yellow powder upon the top, which is the ash always left by the wood charcoal such as is used. No ash, however, is usually seen, and no carbon dust has been burnt.

It must be borne in mind that the filaments now in the crucibles are very different things from what they were when put in. They are now very brittle and easily broken. Consider for a moment the condition in which they now are and it will be understood that great care must be used in handling.

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of re-publication reserved.

The parchmentised thread and the wooden sticks between the two parts of the carbon block are now carbonised and have shrunk, so that the top or larger piece of the block has sunk down upon the lower part. The parchmentised thread, now carbon, is still in one length wound round and round the carbon block. It is, therefore, evident that it will not do to lift out the block in the reverse manner to that by which it was put in. If this is done, the top or larger block being lifted out, the filaments will probably not have the strength to raise the lower one, which will remain at the bottom of the box, having broken through all the filaments. This would not matter if they were all to break at the lower end. It is, however, an invariable rule with filaments to break at a point which will render them useless. The sliding carbon partitions, however, provide an easy method of safely withdrawing the blocks. The carbon box is lifted out of the crucible and is gently turned on its end, the lid having been first removed. Each block of filaments then rests on one of the thin carbon plates. These are then carefully withdrawn one by one with the blocks of filaments lying flat upon them. The next thing to be done is to get the filaments off the blocks. Great care must be taken in handling the blocks at this stage, because the two parts are only held together by the filaments themselves, the wooden sticks, which originally fitted tightly into the carbon blocks, having shrunk during the carbonisation so as to become quite loose in the holes and no longer serve to hold the two parts together. If the blocks were wrapped in paper or calico the now carbonised wrapping must be undone. This is easily accomplished by cutting it along the edge of the block with a knife, when it can be turned back and the filaments exposed to view. With a pair of scissors the upper side of all the filaments may now be cut across between the two parts of the carbon block. Then with a knife the lower side of the filaments may be cut downwards against the carbon plate upon which they are lying. The round end piece of the block can, therefore, be removed with the tail ends of the filaments. The large part of the block can now be lifted up with all the filaments hanging upon it. They should be perfectly straight, and if they have been skilfully handled there will often be not so much as a single breakage. They may now be tipped off the block into a suitable tray or box and put away until wanted. They must, however, be kept in a perfectly dry place or air-tight box if they are to be kept for any length of time, as they may absorb moisture, with the result that when they come to be heated by a current of electricity they may break, or pieces may chip off, owing to the sudden generation of minute quantities of steam. If filaments are allowed to get into this state the moisture may be removed safely by slowly baking them at a temperature less than red heat. Looped filaments are taken off the blocks in a similar way. The filaments are cut midway between the loops and are then gently pulled off the carbon blocks. There is no difficulty in unpacking flat filaments carbonised between paper or calico. Spiral and other forms carbonised loose in powdered charcoal are more difficult to withdraw without breakage.

The process of joining the carbon filament to the leading-in wires (the wires which support the filament and convey the current of electricity through the glass) is usually called "mounting." It may be carried out in a variety of ways, some of which will now be described.

Platinum wire is always used to carry the current of electricity through the glass bulb to the filament. Platinum is employed because it has a coefficient of expansion nearly the same as that of the glass which is used, and because it will stand the necessary heating in the blowpipe flame without melting or oxydising during the process of "sealing-in." Other metals having a different coefficient of expansion will not do, as the glass will crack at the seal. Various means have been tried to obviate the use of platinum on account of its expense. Several experimenters have claimed to have produced alloys of other metals which may be used as a substitute for platinum. Alloys having about the same coefficient of expansion as glass can undoubtedly be produced, but they are open to the objection that they are unable to stand the temperature of melting glass or the action of the blowpipe flame without

Digitized by Google

melting or burning, so that even if the glass does not crack there is likely to be a leak from the imperfect fusing of the glass to the wire. In order to make a safe seal it is consequently necessary to make a very long one, and extra time and trouble are required. No such method is likely to supersede platinum, as the supply of this metal appears to increase with the demand. The high price to which it rose a few years ago was not maintained, and it seems likely to continue to fall. It takes only a small amount of extra labour and a few failures to cost as much as the very small amount of platinum which is really necessary. If a cheap alloy could be produced, which could be used in exactly the same way as platinum is now used, it would, no doubt, very soon take the place of that metal altogether, but it is a question if any substitute requiring a more elaborate seal will be able to do so. The platinum need only enter the lamp for a short distance. If it is desired that the filament be placed some distance away from the seal, copper wires may be fused to the platinum and the filament joined to the copper. Thin copper and platinum wires may be easily fused together. The ends of the wires are held in a small pointed blowpipe flame. The copper quickly melts and a small bead is formed. While this bead is liquid the hot end of the platinum wire is stuck into it and both are removed from the flame when it is found that they are firmly united. If the wire within the bulb is required to be of some length it will be necessary that it be supported, or the weight of the filament may cause it to bend over. It is easy to stiffen the wires by glass. A coating of glass may be fused on the wires, or a T piece of glass may be used, so that the ends of the crosspiece support the wires, the tail of the T being fused to the bottom of the bulb.

The joint between the leading-in wires and the filament may be simply a mechanical one, the filament being clamped in some way to the wires. A socket may be formed on the ends of the wires and the filament inserted and the socket squeezed tightly upon the filament. If the filament be flat it may be held to the flattened ends of the wires by a small bolt and nut. A split holder, with a ring on it exactly like a small crayon-holder, such as is used by artists, may be used. In each of these methods the filament is held simply by mechanical pressure. All these methods, which were used in the early days of lamp-making have, however, been abandoned as unsatisfactory or too costly. The filaments were apt to work loose, owing to the expansion and contraction with temperature. In the earlier forms of the Lane-Fox lamp a hollow carbon tube was used, into which the platinum wire was inserted at one end and the filament at the other, with some kind of carbon paste to make the joint firm.

(To be continued.)

ECONOMY IN WORKING VENTILATING FANS.

At a recent meeting of the Society of Chemical Industry a Paper was read by Mr. H. G. Watel on "The Application of Air in Motion to Chemical Industry," in which the utility of electrically propelled fans, and the questions of speed and size, were discussed. By what practically amounted to a rough application of the economic law the author arrived at the conclusion that slow speeds are preferable to quick speeds, notwithstanding that for the former a more costly fan will be necessary for any given draught of air.

"Many buy fans because they are a few pounds or shillings cheaper than others, and think that they have made a good bargain and saved money, without the slightest thought that in moving such a mobile and compressible matter as air there are all sorts of considerations, such as the slip of the air in the fan, and that the cost of the fan is a small matter compared with the cost of the power expended in driving it. For instance, a fan costs £25 and takes 2½ H.P. to drive it with a duty of 30,000 cubic feet of air per minute. Another fan costs, say, £20, displaces the same amount of air in the same time, but takes 3 H.P. to drive it. As every horse-power costs from £10 to £40 per annum, according to the size of the engine producing it, whether it is one of 40 H.P. or of 4 H.P., say an average of £25 per annum, then the additional half horse-power costing £12. 10s. being added to the cost of the fan, makes the relative expense even at the end of the first year £87. 10s. for the fan which originally cost the most money, and £95 for the cheaper fan, which will in addition be wasting continually £12. 10s. per annum in every successive year, even if it can move the volume of air or do the work. If I emphasise this by saying that I have tested fans of the same dimension, where one took not only 3 H.P., but nearly 12 H.P., to drive it, instead of the 2½ H.P. of which I have just spoken, it will at once be seen that the cost of the "cheaper" fan at the end of the first year would amount to £300, as against the cost up to the same period of its "dearer" rival of £87. 10s., and all to try to save £5 in tangible cash. There is also another point here to which I wish to draw your attention, which is, that if you can displace 15,000 cubic ft. of air per minute for 1 H.P. you are doing excellent work, and that fans professing to do nearly this amount of work per man-power, or, say, 150,000 cubic feet per horse-power, will, when you come to test them scientifically, not do what you may have expected of them. It always costs much more to move the same volume of air at a high velocity than at a low one; 1½ H.P. expended on a 36in. fan costing, say, £17 will move 14,000 cubic feet of air per minute; 1½ H.P. expended on a 60in. fan costing £37 will move 21,000 cubic feet of air per minute. At the end of the first year, still taking the horse-power at £25 per annum, the 36in. fan will have cost £54. 10s., and the 60in. fan will have cost £74. 10s. With the smaller fan each 1,000 cubic feet of air per minute will have cost £3. 17s. 10d., with the larger one the 1,000ft. of air will have cost £3. 16s. 9d., and every following year half as much air again will be displaced without extra cost, and, therefore, with corresponding economy. Therefore, it is at once apparent that it is generally a false economy to employ a small fan driven at a high-speed; on the contrary (except for special purposes where some amount of pressure is necessary), or to drive any faster than is needful for the purpose to be attained. This is due to the fact that air at double the pressure takes twice the power to move it, and more, and at three times the pressure it takes three times the power, and more, and so on."

The best peripheral velocity, or the best speed of rotation, has not been investigated by the author, or, at any rate, the investigation is not contained in the Paper. It could, of course, be calculated if the variations of prime and working cost with the speed were known. But, whatever its actual figure, it certainly will not be a high speed; it may be a very low speed. The result of this is that the best diameter for a fan of given power will be very large; large, that is to say, when compared with the sizes very commonly met with. The author does not appear to have taken the extra cost in fitting the fan, consequent on the large diameter, into account in his calculations. The larger size will necessitate more expensive work in adapting the fan to the place where it is to work. This will tend to keep the size down; but will probably not make any very considerable difference. Another effect of the increase in diameter will be to make it more convenient to apply the driving power to the rim of the fan, as is done in the Blackman electric fan, instead of to the spindle. A third, and very valuable effect, will be that there will be far less violent motion of the air immediately in front of the fan, and consequently less inconvenience to persons who may be there.

The Utilisation of Water Power on the Moselle.—In the Foreign Abstracts attached to the *Proceedings* of the Institution of Civil Engineers there is an interesting note with reference to the canalisation of the Moselle and of a short length of the Saar, which will form a connecting link between the canal systems of France and Germany, and will provide a most improved channel for the conveyance of iron and other materials. The annual traffic, over the length of 250 miles, has been closely estimated at 2,000,000 tons. Between Metz and Coblentz the total fall is 330ft., and this, in forty locks, gives an average fall of 8ft. 3in. per lock. The normal dimensions of the locks are: length, 362ft. 6in.; breadth, 32ft. 9in.; depth, 8ft. 3in. The water required for the series is therefore about 2,800,000 cubic feet, which at the normal level of the river is equivalent to twenty minutes' flow of the current. Each lock is constructed at the end of a weir; and, under the above conditions, a turbine at an effective power of 75 per cent. would develop 2,000 H.P., or a total for the length of the channel of 80,000 H.P. For a great part of the year this power would be increased by 50 per cent., and by adopting electric transmission of the power thus developed it would not be necessary for factories and works to be established on the river bank, but the power would be conveyed to any required point. The capital value of this power at its minimum and at its local rate would be £1,200,000, and the cost of the entire work is estimated at £2,000,000. It is proposed to deal in a similar manner with the Saar, the Lahn, the Lippe, the Ruhr, the Main, and other rivers.

A 30-TON GEARLESS ELECTRIC LOCOMOTIVE.

We have received from the General Electric Company, of New York, particulars of a new electric locomotive which they have recently designed. We understand that this is the largest electric locomotive which has been manufactured by this Company; and it is claimed that it is the first electric locomotive of any considerable size in the United States. The gross weight of the locomotive is 30 tons, which is distributed among the four driving wheels, so that the adhesion of the full weight is utilised. The dimensions of the cage and frame, as shown in Fig. 1, are: length, 16ft. 6in.; width, 8ft. 4in.; and height,

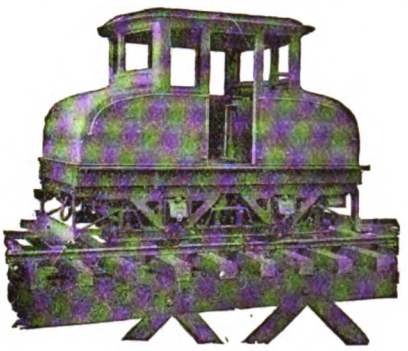

FIG. 1.

11ft. 6in. The driving wheels are 44in. in diameter, and the draw-bars are set to a height of 2ft 6in. from the top of the rail. Fig. 2 gives a perspective view of the motor truck. There are two motors, one on each axle, coupled direct to the axles; and the motors are supported on spiral springs resting on the side frames. By this method of suspension the wheels are free to adjust themselves to irregularities

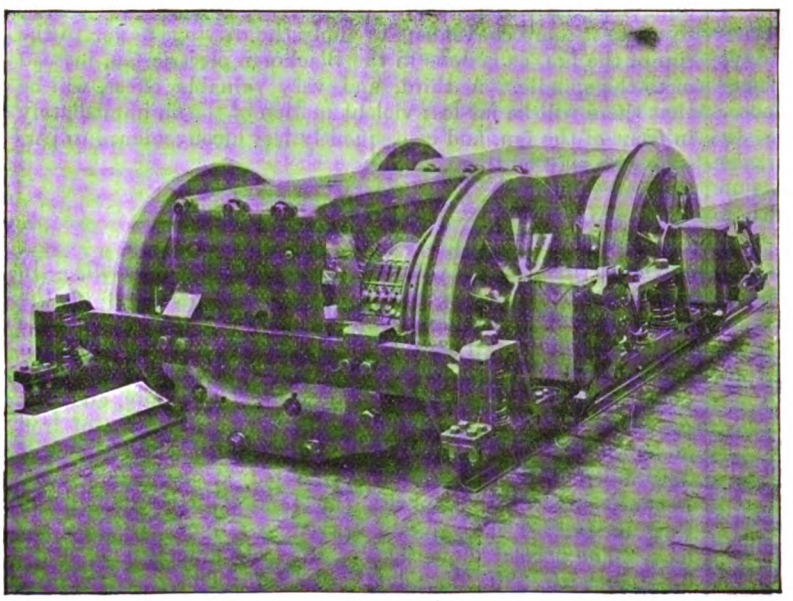

FIG. 2.

in the track. The motors are designed to exert a draw-bar pull of 12,000lb., and the normal speed of the locomotive is 30 miles an hour. It seems probable that the draw-bar pull of 12,000lb. is the estimated starting effort; in which case the normal pull at full speed would be between 900lb. and 1,200lb. At a speed of 30 miles an hour, this would represent a working power of from 70 to 90 H.P. The motor armatures are of the ironclad type, having each separate winding embedded in a mica-lined slot cut into the curved surface of the laminated iron armature core. At starting, the two motors are controlled by a so-called series-parallel controller, which is found to give a very satisfactory start.

The locomotive is provided with two air-brakes, supplied with air by means of an air-pump driven by a small motor. The air-pump also works the whistles. The air-pump has an oscillating cylinder, and a piston having a 6in. stroke; and it is capable of supplying about 3½ cubic ft. of air per minute, at a pressure of 70lb. per square inch. The pump motor is controlled by a special rheostat, which, by an intermediary device, is worked by the pressure of air in the air chamber.

NOTE ON A DETAIL IN PARALLEL WORKING OF ALTERNATORS.*

BY W. M. MORDEY.

In a recent Paper, "On Testing and Working Alternators," I ventured to incorporate a brief account of the principles on which I and my colleagues have acted for some years when dealing in practice with the parallel working of alternators.† In the course of the discussion on the Paper a criticism was made on a certain point, and was met only very briefly. As the matter is of interest, for reasons both of practice and of principle, it may prevent misunderstanding if I allude to it a little more fully, especially as Mr. Swinburne—my critic on the detail in question—has explained his views to me at length, and insists, on theoretical grounds, that my account of the supposed facts must be wrong. Theories may best be tested by applying them to definite and clearly ascertained actions.

The point is this: I stated in effect that two similar alternators similarly excited, driven by separate engines, could be run in parallel, and that, by sufficiently reducing the supply of steam to the engine driving either alternator, the current from that machine could be reduced to zero, or practically zero, without alteration of the excitation. I explained that in taking an alternator out of parallel the steam should be reduced till this condition was reached, and that the armature should then be switched off: and that in putting an alternator into parallel with another the engine should have only enough steam to drive the machine at the synchronous speed; that when switched in, the alternator will "merely keep in step, doing no work on the external circuit, and receiving no power from that circuit. This will be shown by its ammeter, which will show that no current, or only a very small current, passes between the machines." And that "the individual regulation of current (that is, of load) of each alternator is entirely by control of the steam supplied to each engine, and the regulation of the E.M.F. as a whole is by the control of the excitation simultaneously affecting all the alternators." This was criticised by Mr. Swinburne, who said that I was mistaken, that in order to get the current down to zero, or practically zero, the excitation must be lowered till the armature gave the station pressure, otherwise the no-load current must be large enough to reduce the armature pressure, by armature reaction, to equal the station pressure. Before switching alternators out of parallel I had been in the habit of reducing the current to "practically zero" (that is, to 3 or 4 amperes in a 50-ampere alternator, the ordinary ammeters not usually reading lower than this) without altering the excitation. Therefore I had some difficulty in believing it to be impossible.

The question, apart from all theories, is simply this: Is it possible or practicable, by reducing the steam, without reducing the excitation, to reach the condition that "the ammeter shows that no current, or only a very small current, passes between the machines"? This question was put to several engineers engaged in the actual running of alternators, and the following replies were received:—Mr. Shepherd, works manager to the Bournemouth Company, writes: "I find no difficulty whatever in reducing current practically to zero by means of governor and throttle valve. I do not alter field excitation of the machine before switching off, as it is unnecessary." Mr. Johnson, manager and engineer of the Sheffield Electric Light Company, writes: "We can and do reduce the current to practically zero, when switching off, by reducing the steam supply. We do not alter the field excitation of the machine before switching it off." Mr. Clirehugh, engineer to the central station established by the British Insulated Wire Company at Prescott, says: "We succeed in reducing the current practically to zero by means of the throttle valve without reducing the excita-

† See *The Electrician*, Vol. XXX., March 10th, p. 546.

Digitized by Google

tion. A slight flicker is, however, observable on the lamps, which is avoided if we reduce the excitation." Mr. G. C. Sillar and Mr. A. J. Lawson, two of my colleagues, state, with reference to five 2,000-volt 100-kilowatt alternators installed by them at Bangkok: "The alternators were excited in parallel from a common exciter. When about to switch off, we reduced steam at the stop-valve until the current from the machine was 4 or 5 amperes; probably we could have got the current lower, but we never tried. The excitation was not altered until after switching off. We ran various numbers of alternators in parallel, up to five, according to the load."

In dealing with this matter in a broad and general way it is not necessary to refer to such matters as the small difference of excitation necessitated by variations in resistance between cold and hot machines. I have referred to that elsewhere. It is easily provided for by a small resistance in each alternator field, but even that is a refinement, and not a necessity, and does not affect the question at issue, as we frequently work without it.

It must be understood that, as my experience has been principally with my own alternators, the foregoing remarks are not to be taken as applicable to machines of other design; they may or may not be.

PATENT LAW PROCEDURE IN THE UNITED STATES.*

The attention of Chambers of Commerce has of late been directed to a proposal that the English patent laws should be amended with a view of making them, so far as relates to preliminary examinations, analogous to the law and practice at present in force in the United States. A correspondent, well able to speak from the professional standpoint on British practice, and who also has a knowledge of American procedure, examined this proposition, with others, in "Notes on Certain Proposals for Patent Law Reform," which appeared in our March issue.† It was pointed out then that those who were urging the adaptation of English methods to the American standard were apparently not sufficiently informed of the grievances existing even in the United States. We have now received from the other side of the Atlantic a communication which strengthens the opinion that care is necessary in seeking for the introduction of the American system into this country; and, inasmuch as our correspondent speaks with that authority which can alone be acquired by practice under, and intimate acquaintance with, the system of which he treats the information he conveys—if it only succeed in inducing inquiry before specific recommendations for reform are made—will, we anticipate, be welcomed.

In the first place our authority states that under the system of administration of the United States Patent Office there are two applications. "One is called a caveat, which is intended to provide the inventor with the means of memoralising the evidence of his invention as soon as the crude idea is conceived, and before the practical operation thereof is sufficiently completed to be embodied in a specification. By this method the inventor secures his device without limitations in a general way. It is then filed in the secret archives of the Patent Office, and, for the space of a year, with a privilege of renewal the inventor is protected to the extent that, should a subsequent application of a subject-matter similar to that of his caveat came into the Office, the inventor will be informed of this fact, that he may with greater expedition complete his device and make his formal application. The utility of this method is manifest in that it gives the inventor the opportunity of officially fixing the date of conception and placing on record the best evidence of the date of invention. It leaves him at liberty also to expose his invention to the public during the process of completion, which is often necessary where the apparatus is of that character that it cannot be performed in secret, or where it is necessary to employ mechanics to carry out the idea. However, it is found in practice that this method is comparatively little used, though in some cases it has been found to be of the utmost importance."

Coming next to the practice of "preliminary examination," this is described as the "practice which makes the issue of the patent dependent on an examination of the state of the art at the time of the application; wherein lies the cardinal difference between the British and United States practice, the former being granted without examination."

The authority we are quoting says "the merits of these two plans have been the subject of much discussion. With the first establishment of our system the statute made it compulsory upon the Government to issue a patent without question, upon application; but it was found by experience that this practice was fraught with many dangers to the public, in that patents would be obtained from the Government which had no merit in fact, and were, indeed, a fraud upon the public. These would be made the subject of speculative values, and the commercial world would oftentimes be greatly deceived by reason of them.

"In view of this state of fact the law was modified by several statutes attempting to rectify the evil, culminating in the general Act of Congress of 1836, under which the Patent Office of the United States was established, and the Commissioner of Patents was given certain definite powers which constituted him a tribunal for numerous purposes relating to patents; that is to say, he was empowered to examine the state of the art, and to ascertain whether the application, as made, was patentable, and to reject or allow the patent as he might deem just, in view of the art. He had power also to determine the priority of invention between conflicting claimants; and out of these conferred rights have grown the great system of original examinations, and Boards or Courts of Appeal, wherein the questions involved may be considered. However, the powers of the Commissioner of Patents are limited to the extent that he is considered a judicial officer for the purpose of granting patents within the limitations of the Statute, and in proper cases his decisions can be reviewed by the Court.

"The patent granted to an inventor is, however, only *primâ facie* evidence of the fact that he is the first inventor, or entitled to the patent. All questions, excepting the formal procedure in the Patent Office, are subjects of review by the Courts of the United States, and in cases where the patent has been procured by fraud in the Patent Office formal questions regarding issue will be considered also.

"It will therefore be seen that there is ground for very serious criticism of the system, for the reason that the inventor is often put to great expense and delay in the procuring of his rights from the Patent Office to find, after his patent is granted; that he has got the same difficulties to contend with in the Courts to fully establish his rights."

The practical working of the system, granting that all difficulties are thrown in the way of the patentee, is somewhat as follows:—The applicant "first files a caveat, briefly describing his invention. He is thereafter notified that another applicant has filed either a caveat or an application for substantially the same subject-matter. He then completes his invention and makes his application in due form. He is then thrown into 'interference,' as it is called, with the rival applicant. For the purpose of determining who is the prior inventor, times are fixed for the taking of testimony, the hearing is had and award granted, from which an appeal may be taken. Then motions may be made for the dissolution of the interference on the ground that it was improperly declared, until, finally, priority is awarded to one of the inventors and his patent is issued. The defeated applicant then proceeds to manufacture and sell the subject-matter of the invention in defiance of the rights of the patentee, and the patentee brings his action for such violation. All the questions which were before the Patent Office, as regards the patentability and priorty of the invention, will be again considered *de novo* in these Courts, from which an appeal may be taken.

"Experience has shown that where large interests are involved, and expense is no object, immense delays can be had by reason of the abuse of this procedure, and where one of the parties has unlimited means and the other not the battle is a very uneven one, and substantial rights may be defeated by reason of the poverty of the inventor. Again, a number of cases have been brought to light in the last few years in which a conspiracy has been entered into between rival applicants, whereby their inventions have been tied up in the Patent Office for an indefinite time, going through the roll of appeals, amendments, and motions, until, finally, after the expiration of a suitable length of time, their patents are granted with the privilege of the full term of seventeen years from the date of granting, they having enjoyed, in point of fact, a practical protection during the period of their delays in the Patent Office."

From another source, also American, we are informed that the delays in the United States Patent Office are the subject of general complaint, and there is latent, if not expressed, approval, in influential quarters, of the English system. Confirming the statement we have already set forth above as to the indefinite time inventions lie dormant, our other authority cites instances of tying-up for seventeen years, another for eight years, and several for five or six years. In fact, so far from the American system being an ideal one, which, if adopted, is likely to remove such grievances as are complained of in connection with our method, that system has itself been the object of adverse criticisms and of proposed amendments. The original authority we have quoted declares that many reforms have been attempted, "but there has been so much opposition to the patent system by a certain class of the public that the reformers have feared to attempt radical changes, for the reason that they feared the whole fabric might be undermined."

PARLIAMENTARY INTELLIGENCE.

The Dublin Southern District Tramways Bill.

The Committee of the House of Commons on the Dublin Southern District Tramways Bill have had under consideration the question of introducing into the Bill the model clauses recommended by the Joint Committee in substitution of a clause which had been agreed upon between the promoters and the National Telephone Company. The question first arose on Tuesday, July 18th, and the Committee adjourned the proceedings for the purpose of hearing the views of the National Telephone Company on the subject before finally deciding. Mr. Samuel Hoare was Chairman of the Committee. The promoters were represented by Mr. J. D. Fitzgerald; Mr. Pember, Q.C., appeared for the National Telephone Company, and Mr. Pembroke Stephens, Q.C., for the Dublin, Wicklow, and Wexford Railway Company, who were opposing the Bill. On resuming the proceedings on Tuesday last, Mr. Chandos Leigh, the Speaker's counsel, and Mr. Courtenay Boyle, representing the Board of Trade, were also present.

The CHAIRMAN, in opening the proceedings, said the Committee had again been considering the question, which was rather a difficult one, inasmuch as the Bill came before them under very exceptional circumstances. At the same time the Report of the Joint Committee had been laid upon the table of the House but not at present discussed. At the previous sitting, the Committee made some suggestions as to the possibility of settling matters of difference between the parties, but apparently there seemed to be some difficulty in carrying that out, and the question came again before the Committee now as to whether it was possible or not to introduce the model clauses. They feel, however, that they could not come to a decision until they had heard counsel, and they fully realised that there would be considerable difficulty in altering those clauses if they were to be introduced into the Bill, so that so far as they could at present judge, the clauses would have to be introduced very much in their present shape, though the Committee were quite ready to hear argument on the point. On Clause 5 the question of the number of years to be inserted would necessarily have to be a matter for consideration.

Mr. PEMBER said the Telephone Company had had to consider the matter very seriously from their own point of view, not only as an independent question affecting their own interest, but also from the point of view of having given an undertaking in the other House. His clients had set to work to see if they could do something in the direction of the model clauses with a view of bringing that Bill, by anticipation, into line with anything which might be done by the Board of Trade hereafter with the sanction of Parliament. Their difficulty was that it was premature to put into operation the model clauses, because they were not a final declaration of what Parliament intended to do, and that they must be read by the light of the recommendations of the Committee. They had suggested slight modifications in the clauses, and being met in a proper spirit by the promoters, they had agreed upon such modifications of the model clauses, which, in spite of what the Chairman had just said, he hoped the Committee would see their way to accept. The learned Counsel then read the correspondence which had taken place between the Parliamentary agents, the objections of the Company being stated in the following letter, dated July 24th, from the agents to the Telephone Company:—

"Our clients, the Telephone Company of Ireland, are anxious not unnecessarily to prolong the discussion before the Committee on the question of the protective clauses, and with this view they have been anxiously considering the suggestion made by the Chairman of the Committee on Tuesday last, whether it was possible for our clients to come to an understanding with the promoters on the subject. Our objections to the proposal to insert the clauses suggested by the Joint Committee in the pending Bills and Orders are twofold.

"1. The resolution of the two Houses appointing the Joint Committee directs that Committee to consider and report on the restrictions and provisions to be inserted in the grant of statutory powers to use electricity. The Committee have in effect, by sub-section 3 of the proposed clauses, relegated to the Board of Trade the duty of settling those restrictions and provisions by schedule to the Act or Order, or by subsequent regulations, and to insert the clauses suggested by the Joint Committee unaccompanied by such schedule, is in effect to insert a skeleton clause leaving the whole matter in the air. If words are inserted making it perfectly clear that any regulations which the Board of Trade may make, say within 12 months from the passing of the Act, shall be treated in all respects as if inserted in the schedule to the Act, and be as binding in all respects upon the undertakers, our clients would be satisfied on this point.

"2. The other point is this: Sub-section 5 contains a very serious limitation on the power of our clients to enforce the provisions of that sub-section by providing that at the expiration of —— years from the passing of the Act they shall have no right of action in respect of the provisions of the sub-section, unless they have taken steps to protect themselves, and the substitution of an insulated metallic return for the present earth return is specifically mentioned. This is a sufficiently serious matter to our clients, however it is looked at; but our clients are not seeking to take exception to the principle laid down. When, however, it is proposed to fill up the blank by reference to Resolution 10, it becomes essential for them to point out that this is to impose on them an impossible task.

"That this was not the intention of the Joint Committee is obvious, because in the prior resolutions they have recommended the use of an insulated return for telephone lines, deprecated the necessary duplication overhead, and recommended that to facilitate the use of these returns the necessary statutory powers should be granted to enable telephone undertakers to lay their lines underground. It is not too much to say that it is impossible in many crowded centres to duplicate the wires overhead, and yet if the clauses are inserted in your clients' Bill, with the blank filled up as proposed, the Telephone Company will have placed upon them the duty (indeed, the necessity) of duplicating their lines without any power whatever of doing it. They therefore submit that to incorporate the 10th resolution into the clauses, while ignoring the previous resolutions which alone make the later one practicable, would be in the highest degree unjust. Our clients, therefore, suggest that the two years should run not from the passing of the Act, but from the date at which the Board of Trade shall certify that the owners of the electric lines, wires, and apparatus referred to, possess reasonable facilities (whether by statutory power, consent from the Local Authority, or otherwise) for the execution of the necessary works. If your clients are prepared to meet the Telephone Company on these two points, they will not press their objection further."

They proposed to insert Clauses 1, 2, and 3, as recommended by the Joint Committee, unaltered, but at the end of Clause 3 they proposed to add "and such regulations shall have the same effect as if included in a schedule to this Act." Clause 3, as drawn by the Joint Committee, presupposed a schedule, but there was at the present moment no such schedule, and to embody Clause 3 *en bloc* without any modification would involve an utter absurdity. By that addition they gave in effect a schedule to the Act, but it would be necessary to make such an alteration for this occasion only, as next year the Board of Trade might have made their regulations, which could be put in as a schedule to the Act. Clauses 4 and 5 they did not touch until they came to the proviso which dealt with the blank number of years. If it had been necessary for him to attach the consistency of the recommendations of the Joint Committee and their clauses, he should have pointed out that it was not of the slightest use filling up the blank with any number of years after the passing of this Act, because it would have been inoperative if the promoters only waited for that period of years before they put their Act into execution. They had, therefore, agreed to modify the clause in this way: "Provided also that nothing in this sub-section shall operate to give any right of action in respect of or to protect any electric wires, lines, or apparatus or the currents therein, unless in the construction, erection, maintaining, and working of such electric wires, lines, or apparatus, all reasonable and proper precautions, including the use of an insulated return, shall have been taken to prevent injurious interference therewith or with the currents therein by other electric currents." That dealt with the matter as a compromise, and in the only way in which it could be dealt with any show of satisfaction to the parties on the present occasion. The whole thing being premature, so long as it was not licked into shape by Parliament or the Board of Trade, he hoped the Committee would not refuse to deal with this particular case in that special manner.

Mr. FITZGERALD (on behalf of the Promoters) intimated their acceptance of Mr. Pember's propositions.

The question arose as to the intervention of the railway company in the discussion, and

Mr. FITZGERALD said he thought they could not object as the railway company did not object to the model clauses, and all the alterations that were suggested were in favour of the telephone company or the railway company, as the case might be.

Mr. PEMBER said they must look to some of the recommendations of the Joint Committee apart from the clauses being carried out, and one of the most important of the recommendations was that facilities should be given to insulate their wires by putting them underground, while they also deprecated very much the multiplication of wires overhead. Until they got facilities for putting the wires underground it was perfectly clear if they duplicated at all it must be overhead, and that was against one of the strongest recommendations of the Committee. It was only under the special circumstances of the case that he asked the Committee to depart from the clause.

The CHAIRMAN asked if Mr. Pember would have any objection to the retention of the clause "provided also at the expiration of *three* years," that being the period they proposed to insert, if they afterwards inserted a further proviso giving the Board of Trade power to extend the time by an order which should be laid before Parliament.

Mr. PEMBER suggested that that was adding to the expense and machinery. His own amendment, he thought, was simpler, and Provisional Orders were expensive.

Mr. CHANDOS LEIGH said that what the Chairman suggested would not be any expense.

Sir COURTENAY BOYLE said that the order suggested was not a Provisional Order, but a documentary declaration.

Mr. PEMBER said that if it was understood that the Board of Trade had a perfectly free hand, in consequence of any circumstance brought to their notice, to extend the time, he should not object. So long as it was not a Provisional Order to be confirmed by Parliament, and which would give rise to a repetition of the wrangle over and over again, he was satisfied.

On the question of whether the period to be named in the clause should be two or three years,

Mr. PRITT (representing the City and South London Railway Company), in reply to the Chairman, said that the blank had been filled up in that case by the insertion of three years.

It was then agreed that the clause should be amended by the insertion of "three" years, and with a proviso that the Board of Trade should have power to extend the time by an order, and that in every such case the Board of Trade should make a special report to Parliament notifying the making of such order. The other modification suggested by the Telephone Company were agreed to.

Mr. PEMBER said that his clients were rather anxious that he should state that they did not wish their action on this particular occasion, which they considered special to themselves, to be quoted against them as a kind of precedent in other Bills, by saying, "You submitted to this in one case and are precluded from attacking the model clauses in other

Digitized by Google

cases." They wished to preserve their full freedom of opposing the model clauses on their merits or demerits at any future time; but the present case was special, because of the fact that the clauses had not yet been finally adopted by Parliament, and on account of the undertaking into which they had entered in the other House.

The Committee then went through the clauses of the Bill, reserving till later their sanction of the precise wording of the protective clauses.

Before Lord Morley's Committee on Unopposed Bills the question of substituting the model clauses instead of the agreed clauses was raised on the Blackpool Tramways and London, Deptford, and Greenwich Tramways Bills, in respect to which powers to work by electricity are taken, and the Committee reserved their decision. In the case of the City and South London Railway Bill, providing for the extension to Islington, it was agreed that the clauses recommended by the Joint Committee should be inserted.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 14, 1893.

Incandescent Lamp Litigation.—The arguments in the incandescent lamp suit at Milwaukee (Wis.), was submitted to Judge Seaman on July 8th, and an opinion has been promised for July 17th. Very little new matter was brought up, although points previously used were greatly elaborated. A remarkable feature of the trial was the changing about of witnesses, several of whom directly repudiated their testimony given on previous trials. A sensational feature was the testimony of Goebel's son, who contradicted his sworn testimony on a previous trial, and swore that he had made the lamps upon which the Goebel claims were based, just previous to the Beacon case; scarcely less sensational was the production of an affidavit by a hitherto unknown son of Goebel's, who strongly sustained his father's claims. Many charges of bribery and perjury are being made, and it is probable that some of the witnesses will be prosecuted.

The Forthcoming Electrical Congress.—Foreign delegates to the Electrical Congress are beginning to arrive, but as yet only one full Commission seems to have been named—that of Great Britain. There is one member lacking from the French Commission. Dr. Helmholtz, for Germany, and Dr. Sahulka, for Austria, are the only others that are known to have been appointed to the Congress. Practical electrical engineers are agitating to have the Electrical Congress define the nominal candle-power of arc lamps in terms of watts, but it seems to be doubtful if any formal action can be taken. Frequent disputes have arisen between municipalities and electric lighting companies, and in the absence of any authoritative definition "experts" have generally made matters worse through their testimony.

CORRESPONDENCE.

THE VELOCITY OF GRAVITATION AND A RESISTING MEDIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It has probably often been noticed before, but if so there is no harm in noticing it again, that the consequences of a finite velocity of propagation of gravity, and the consequences of a universal medium which resists the motion of matter through it, tend to neutralise one another; so that it is just possible that both circumstances may really exist without having been noticed.

Gravitational aberration would result in an accelerating tangential force pulling the planet or satellite in the direction in which it is going, and its amount would vary directly with the velocity and mass of the planet. The effect of this force, if uncompensated, would be to gradually make the body move more slowly and get more distant from its centre of force.

A resisting medium, on the other hand, would pull back the planet by exerting on it a retarding tangential force, which if uncompensated would make it move more quickly and approach its primary.

It is probable that such a force, due to etherial viscosity, would be proportional to the first power of the relative velocity, and since the ether has been shown by optical facts to penetrate material bodies, and thus act on each atom of which they are composed, the force is not unlikely to vary also with the mass of the moving body.

Hence the compensation, if ever existent by reason of some unknown relation among the constants, would seem to hold fairly well for all bodies and at all speeds, except when the orbits are quite eccentric, but not excepting the case of an absolute drift of the ether past all bodies; though the effect of this last would need a little discussion to make it clear. Suffice it to say that if the ether possessed no viscosity, no aberrational disturbance to wave motion would be caused by such drift, whereas if the ether stream accelerated a planet viscously it would also curve the rays of force reaching it, in such a way as to make them pull it partly backwards.

The very interesting article by Mr. Heaviside in your issue of July 14th, on possible gravitational stresses and their propagation in time, suggests my sending this note to you.—Yours, &c., OLIVER J. LODGE.

INSTRUMENTS FOR MEASURING ALTERNATING MAGNETIC FIELDS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In view of your last week's note on M. D'Arsonval's instruments for measuring alternating magnetic fields, it may interest you to know that some 15 months ago I designed a similar instrument to obtain their shape. It consists essentially of an air thermometer with a flat bulb, in which is fixed a *thin copper disc*. Currents will be induced in this in all positions except that in which the plane of the disc is parallel with the (local) direction of the field. It may be used in two ways. In any one position it may be rotated to give a minimum and a maximum heating. In the first, the plane of the disc indicates the direction of the field; in the second, it is 90deg. removed.

Only one instrument was made, and that was too large, and so did not act well for my purpose. I hoped to apply it to examine some of the fields produced in the experiments of Dr. Fleming and Prof. Elihu Thomson. Pressure of other work has prevented further progress. The instrument is useful for demonstrating to elementary students the essence of magneto electric induction.—Yours, &c., W. HIBBERT.

14, Goldhurst-terrace East, N.W.,
July, 1893.

LEGAL INTELLIGENCE.

Re Slater Lewis.

This bankrupt, who is well-known in connection with the Birmingham Telegraph Factory, &c., and who was described as of Castle-hill, Ealing Dean, London, applied at the Birmingham County Court on Thursday last week for his discharge. He was described as a mechanical engineer. The Official Receiver (Mr. Sharpe) reported that the receiving order was made on the petition of Messrs. Archdale and Co., in April, 1892, and the bankrupt's statement of affairs showed liabilities of £1,613, which were all contracted since August, 1891, with the exception of about £100. Assets of £8 had been realised by the Official Receiver from the sale of a watch and chain, and £41. 13s. 4d. in respect of instalments of £4. 3s. 4d. a month, which bankrupt had voluntary paid out of his salary of £300 a year. Particulars of the early career of the bankrupt have previously appeared in *The Electrician*. In 1890 he formed, in conjunction with Messrs. Fowler, Lancaster, and Co., the Birmingham Telegraph Factory (Limited), and was appointed Managing Director. He remained with the Company till July of the next year, when he was approached by Mr. Richard Tangye with a view to forming a new electrical company. The negotiations fell through, and Mr. Tangye gave the bankrupt £750. Bankrupt then paid some debts, and with £525 left, started in business at Aston. In November, 1891, he floated a company under the name of the National Telegraph Works Company, the capital of which was to be £5,000. Bankrupt took 525 shares of £5 each, and six of his *employés*, with a share each, formed the necessary number of shareholders. No other shares were allotted, but debentures amounting to £800 were issued, and formed the capital of the Company. Most of the debts were incurred previously to the formation of the Company, and the stock, &c., bought before were transferred to the

Digitized by Google

Company, which was to pay his creditors. In February, 1892, the Company was wound up, but the assets did not realise sufficient to pay any dividend to creditors. Mr. Sharp submitted that in November, 1891, the bankrupt must have been aware that the capital to float the Company had not been subscribed, and he ought not to have launched out as he did until he had satisfied himself that the money would be forthcoming. He had undoubtedly contributed to his bankruptcy by rash and hazardous speculation.

Mr. RICHARDSON (for the bankrupt) said the bankruptcy was due entirely to misfortune, and that the bankrupt all through the transactions acted in a perfectly *bonâ fide* manner.

Mr. BRADLEY (as representing Messrs. Archdale and Co.) said their complaint was that bankrupt got goods from them on credit, and without their consent transferred them to a company without assets. He might, having thus divested himself of everything, have walked off had not the petitioning creditors stepped in at their own cost.

His HONOUR asked what the bankrupt was now doing, and

The OFFICIAL RECEIVER read the following letter:—"W. T. Goolden and Co, Woodfield Works, London. Sir: *Re* J. Slater Lewis. Mr. J. Slater Lewis has been employed by my firm for the last fifteen months in the responsible position of works manager. I have seen a great deal of Mr. Lewis, and have formed a very high opinion of his character. He has proved himself to be a man of great energy and ability, and in all his relations with me of the most scrupulous honour. I consider him to be quite incapable of any questionable conduct.—I am, &c., WALTER T. GOOLDEN."

His HONOUR said no doubt the bankrupt fully and honestly believed that the company would be a success, but, nevertheless, he must say that when a man wanted to start a company and incurred debts on behalf of such future company, he was really risking his creditors' money instead of his own. Rightly or wrongly, under the existing law, a man could practically start a company of which he himself was the sole manager; in fact, the company itself. In this case the six other requisite persons took only a nominal share each, so that practically bankrupt was the company The law at the present time was in a curious and anomalous state. A man could incur debts, he could turn himself into a company with nobody else substantially a member of the company, and he could transfer all the property he had to a perfectly different set of creditors to those whom he previously owed money. This is what happened in the present case. He did not complain of the bankrupt for the curious state of the law, and he dared say bankrupt did not contemplate that curious state of things. The Company, although intended, no doubt, to be a *bonâ fide* one, did not go to allotment, and the prior creditors received no satisfaction. He hoped that the possibility of such a position arising again would soon be prevented. The law was in a very unsatisfactory state, and it was desirable that it should be taken into consideration, and a remedy discovered. He considered the bankrupt in this case intended to act honestly, but, under all the circumstances, his discharge would be suspended for three years. He was bound by the Act to suspend for at least two years any bankrupt who had not paid 10s. in the pound in a previous failure. If the bankrupt in the future found himself in a position to make a good offer, as there was rashness but no fraud in the case, he (the Judge) would be prepared to reconsider his order.

Mr. RICHARDSON replied that probably an application on those lines would subsequently be made.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Vestry of St. Pancras invite tenders for extensions of their electric lighting works, including the building of an underground sub-station at Regent's Park, and the supply of storage batteries, armoured cables, bare copper strips, cast-iron pipes, laying mains, &c., and the providing of boilers, engines, dynamos, &c,, for the West St. Pancras Central Station. Conditions, specifications, and schedules of quantities can be obtained of Prof. H. Robinson, 13, Victoria-street, Westminster, S.W., and tenders must be sent in to Mr. T. Eccleston Gibb, the Vestry Clerk, the Vestry Hall, Pancras-road, London, S.W., not later than 12 o'clock, on Thursday, August 10th.

——— The Vestry of St. Pancras also invite tenders for various works in connection with the East St. Pancras Central Station, King's-road, N.W. Contract No. 1 is for the building of a chimney shaft, and Contract No. 2 for a subway under Georgiana-street, and for minor works. The conditions, specifications, &c., can be obtained of the Borough Engineer, Vestry Hall, St. Pancras, and tenders must be sent in to Mr. T. Eccleston Gibb, the Vestry Clerk, not later than 12 o'clock on Wednesday, August 16th.

TENDERS RECEIVED.—Tenders have been received by the Electric Lighting Committee of the Middlesborough Town Council for lighting the municipal buildings and Town Hall by electricity from the Brush Electrical Engineering Company, Limited (London), Messrs. Stevenson and Cowper (Middlesborough), and Messrs. J. H. Holmes and Co. (Newcastle). The tender of the latter firm was the lowest, the amount being £2,930, but after discussion it was decided to recommend the Council, in view of the present financial position of the town, and some prospective heavy outlays, not to entertain the question of electric lighting at present.

TENDERS ACCEPTED.—The Metropolitan Asylums Board have, subject to the assent of the Local Government Board, accepted the tender of the Electrical Power Storage Company (Limited), for the supply of apparatus for lighting by electricity the store rooms on board the "Atlas" and the "Endymion," the amount of the tender being £124. 16s. 11d.

——— The Watch Committee of the Worcester Corporation, at their meeting on Friday, decided to recommend the Council to adopt the Powick Mills site for a central station, and to accept the tender of a Birmingham firm for the erection of the building.

——— The Electric Lighting Committee of the Nottingham Corporation have accepted the tender of Mr. F. Messom, of Nottingham for the erection of the central station in Lower Talbot-street at the price of £10,209.

APPOINTMENTS VACANT.—The Electric Lighting Committee of the Borough of Kingston-upon-Thames are about to appoint a resident electrical engineer to take charge of their electric lighting works, and to have the management, the salary to commence at £150 per annum. Further particulars are given in our advertising columns, and applications must be sent in to Mr. Harold A. Winser, the Town Clerk, Clattern House, Kingston-upon-Thames, before noon on Thursday, August 3rd.

DISSOLUTION OF PARTNERSHIP.—The partnership between Henry Bowes Scott and Charles Robert Western, carrying on business at Broadway-chambers, Westminster, as civil and mechanical engineers, has been dissolved. The business will be carried on by Mr. Western under the old title.

ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT, BERLIN.—We have received an illustrated pamphlet descriptive of this Company's exhibits at the World's Fair at Chicago.

MESSRS. RUSSELL AND CO.—This firm have just issued a new catalogue devoted to a description of engines and boilers supplied by the firm. The illustrations, descriptions, and prices, include nearly all the best-known types. The firm is prepared to supply all kinds of electrical and mechanical plant for lighting and power transmission purposes.

MESSRS. DOULTON AND CO.—This firm announce that their patent conduit for underground electric mains, together with a selection of pottery for electrical purposes, which has been exhibited at their Lambeth showrooms during this week, will remain on view to engineers, on presentation of card, until August 5th.

MESSRS. DRAKE AND GORHAM.—Amongst the recent contracts obtained by this firm is one for the electric lighting work required at the extensive offices of Messrs. Huth and Co., in Tokenhouse-yard, E.C.

MESSRS. VERITY AND SONS.—This firm's Manchester branch are busy installing the electric light all over the city, and have on hand installations at the Free Trade Hall, Royal Exchange, and Free Library, in addition to a number of private orders in the outskirts of the city, and in connection with the Corporation's supply.

MESSRS. JULIUS SAX AND CO. (LIMITED).—This Company have applied to the Court of Common Council for a lease for 80 years of land in Charterhouse-street, on which they would erect a station for the generation of the electric light for the markets. They undertake to surrender the land again to the Corporation if it were required for market purposes, in which event they suggested the Corporation should pay them £7,000 compensation. Some considerable discussion ensued, and finally the petition was referred to the Markets Committee for consideration and report.

MESSRS. CHARLESWORTH, HALL AND CO.—We are informed by this firm that Messrs. Appleton, Burbey, and Williamson no longer represent them as London agents.

PRACTICAL NOTES FOR APPROXIMATE CALCULATIONS.—We have received from Mr. H. A. Mavor, of Glasgow, a copy of a set of rules and formulæ, which he has drawn up, for the purpose of assisting electric light engineers in rough calculations. The rules cover a wide ground, and appear to be based on average practice; they include water power, steam boilers, simple engines, belting, dynamos, storage batteries, conductors, and light. The sheet on which these rules are printed could conveniently be pasted inside a small pocket-book.

Digitized by Google

GAS, WATER, AND ELECTRIC LIGHTING STATISTICS, &c.—Messrs. Watson, Hazell, and Viney forward us a copy of their "Gas, Water, and Electric Lighting Directory for 1893," just issued. The book has additional sections dealing with gas and water companies' statistics, and much of the information given will be found of use to our readers. The price of the book, bound in cloth, is 10s. So far as we have been able to test the information given concerning electric lighting undertakings, it would appear that the opportunity has been missed (seeing that the book is apparently not published until July) of making many corrections calculated to improve the accuracy of the book.

BECKENHAM.—At the last meeting of the Local Board a committee was appointed to undertake the consideration of all matters relating to electric lighting.

BRADFORD.—At their meeting on Monday the Gas and Electricity Committee of the Corporation commenced the consideration of Lord Kelvin's report, a decision in the matter being postponed until the next meeting.

CHESTER.—At the meeting of the Corporation last week the Town Clerk stated that a report had been submitted to the Watch Committee by Mr. W. H. Preece suggesting a site for the electric light station, and recommending the adoption of the low-pressure system, to which could afterwards be added the high-pressure system with alternating currents and sub-stations if a sufficient demand arose. He estimated that the initial outlay would be £15,000. At a previous meeting the Watch Committee had appointed Dr. Hopkinson as Chief Engineer, and had instructed him to prepare a scheme, but nothing had been finally done in the matter. Mr. W. H. Churton remarked that the Committee had been empowered by the Council to proceed so far with the matter, but they had committed themselves to nothing, as they could not accept a tender without the sanction of the Council.

COWPEN.—Mr. Sanderson, the electric light contractor, has been mulcted in penalties for non-supply of the light on one occasion; but as he ascribes the failure to the fact that he could get no water for the boilers, a conference is to take place between him and the Finance Committee.

CRYSTAL PALACE.—Arrangements are being made for the introduction of the electric light throughout the entire building, which will be fully installed at the termination of the present contract.

THE ELECTRIC LIGHTING OF THE MANSION HOUSE.—The Court of Common Council last week passed the account of the City of London Electric Lighting Company for current supplied to the Mansion House for the half-year to Midsummer last, the amount being £449. 18s. 11d.

GOOLE.—An Art Exhibition has recently been held at Goole, which was lighted by electricity. We understand that the light has given great satisfaction, and inquiries are now being made as to the probable cost of its intoduction into the town generally.

HADDINGTON.—At the last meeting of the Town Council the Clerk stated that, regarding the water power at the East Mill, a London firm of engineers had reported that the normal horse-power of the water was not sufficient for the purpose of supplying the power for lighting the burgh, but that it might be supplemented by steam, as had been done in other places. A discussion followed, but a motion to appoint a Committee to consider the question was negatived.

HERTFORD.—The Corporation recently submitted Mr. J. A. McMullen's scheme for lighting the town to Prof. Forbes for confirmation, and he has, we learn, agreed with Mr. McMullen's proposals on all important points, so that in all probability the alternating system of distribution with transformer sub-stations, and gas engines, driven by Dowson's gas, will be selected.

KILLARNEY.—At the meeting of the District Lunatic Asylum, last week, Mr. Walter Leake submitted his report upon the proposal to light the Asylum by electricity. It will be remembered that the Asylum Board a few weeks ago accepted a tender from the Killarney Electric Light Company (Limited) to supply the light at a cost of £185 per annum. Mr. Leake recommended that this tender be modified so that the current should be taken at 4¾d. per unit, and that a guarantee be given by the Board that the amount of current consumed should not be under the value of £150 per annum. He had carefully examined the Asylum, and came to the conclusion that 295 8-c.p., 251 16-c.p., 9 32-c.p., and 6 100-c.p. lamps would be required. To carry out the installation properly a sum of £1,200 should be expended in fittings, &c. It was resolved that a copy of the report be sent to the Company, and that they be asked to tender for the supply and erection of the fittings, &c. A notice of motion was, however, given for the next meeting that the whole matter of the electric lighting should be reopened and further considered.

LEICESTER.—The Ratepayers' Association have decided to appear before the Commissioner who is shortly to hold an inquiry on behalf of the Local Government Board respecting the subject of the electric lighting of the town, and to oppose the proposed scheme.

MANCHESTER.—The Special Sub-Committee of the Corporation, appointed with reference to the subject of telephones and electric traction, reported at the last meeting of the City Council that in pursuance of their instructions they united with other municipal Corporations of England and Scotland in appearing by counsel and giving evidence before the Joint Committee of both Houses of Parliament dealing with the matter. The clause which the Joint Committee adopted, and which was to be inserted in all bills or Provisional Orders which authorised the undertakers, other than electric-lighting undertakers, to use large electric currents, was more favourable to electric traction than the form of clause contended for by those interested in telephone wires. The results of the action by the Municipalities had been, generally speaking, satisfactory. They thought that the recommendation of the Joint Committee as to placing the telephone wires underground would render it necessary for the Municipal Corporations to consider what action should be taken by them upon any Bill in Parliament which might be introduced for dealing with the subject. On the motion of the Lord Mayor, the report was adopted.——In reference to a report which appeared in a contemporary last week that the fire which occurred at the Manchester Free Library was caused by the electric lighting work, we are requested to state the report is false; the electric light has not been installed nor will it be for some weeks. It is more than likely that the fire arose through the upsetting of a lamp used by the workmen engaged in the dome of the building; and we learn that Messrs. Verity and Sons, who have the electric lighting in hand, have been exonerated from all blame in the matter. The daily press was, no doubt, the source of our contemporary's information, but where it is possible to obtain confirmation or denial of such statements it is most essential in the interests of the industry that every effort should be made to do so. Doubtless the false report will be made the most of by the opponents of the electric light.

OSWESTRY.—The Town Council have decided not to oppose the proposed application of the Oswestry Electric Light and Power Company to the Board of Trade for a Provisional Order.

PLYMOUTH.—Major-General Hutchinson, R.E., C.B., held an inquiry at Plymouth last week concerning an application of the Corporation to the Board of Trade for sanction to borrow a further sum of £13,000 for the purpose of fully equipping the tramways which they recently purchased from the Plymouth Tramways Company. The Town Clerk, in supporting the application, said that as regarded the question of utilising electric motive power the Council had decided not to adopt the overhead system, and the gradients were so steep on the main line that that portion could not be worked on the accumulator system. It was possible, however, that the lines in the lower part of the town, which had been sanctioned by the Board of Trade, and which they hoped would shortly be sanctioned by Parliament, might be worked advantageously by electricity.

REDDITCH.—The Local Board have instructed Mr. J. A. McMullen to advise them on electric lighting matters generally, and to prepare a complete scheme for the town installation.

SEVENOAKS.—The Local Board at their last meeting decided not to oppose the proposed application to the Local Government Board by Mr. Hemmant for a Provisional Order for lighting the town.

SHREWSBURY.—In March, 1891, the Town Council transferred to the Shropshire Electric Light and Power Company (Limited) their powers under a Provisional Order, with the understanding that the Corporation might purchase the rights and property of the Company at the end of 7, 14, or 21 years. The Company have recently requested the Town Council to extend this time, so that 21 years should be the minimum period for purchase, and at a meeting of the Council last week it was decided to extend the period to 21, 28, or 35 years.

WEYBRIDGE.—The Chertsey Rural Sanitary Authority last week resolved to draw the attention of the Weybridge Electric Supply Company (Limited) to the section of their Order which limits the time for removing the overhead wires, and to inform them that the Authority could not consent to the wires remaining above ground in contravention of that Order. It was stated that the contract originally entered into had only about 14 months to run, and if the Company failed to comply with the terms of the Order it would be necessary to make some arrangements for the lighting of the parish.

WOLVERHAMPTON.—Mr. S. J. Smith, C.E., held an inquiry on Tuesday at the Town Hall on behalf of the Local Government Board with regard to an application by the Town Council to borrow, amongst other sums, £1,927 for electric lighting purposes. There was no opposition, and the proceedings were merely formal.

WREXHAM.—The Town Council on Tuesday resolved to open negotiations with the Wrexham and District Electric Supply Company (Limited), as to the taking over of that Company's Provisional Order. They will not, however, adopt or take over any contract for work in connection with the supply of electricity that may have been entered into by the Company.

10,283. HOFMANN. Electrode plates for secondary batteries.

10,501. PRICHARD. Heating liquids by electricity.

COMPANIES' MEETINGS AND REPORTS.

Globe Telegraph and Trust Company (Limited).

The twentieth ordinary general meeting of the Globe Telegraph and Trust Company (Limited) was held yesterday at Winchester House, Old Broad-street. Sir John Pender, G.C.M.G., M.P., presided.

The SECRETARY (Mr. Sidney Collett) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: I shall, as usual, make a few remarks supplementary of the report, so that you may have a thorough knowledge of what has been doing since I last had the pleasure of addressing you. The receipts for the year ended July 18th inst., after payment of expenses, amounted to £188,931, as against £192,243 last year, or a decrease of £3,312. This decrease, which I may say is but a small one considering the general depression which has existed during the past year, is accounted for by the fact that we have received somewhat reduced dividends from four or five of the companies in which we hold investments. On the other hand, there are two or three companies who have given us a better return this year than we received in the corresponding period of 1892. This, gentlemen, enables us to recommend to-day the payment of a dividend on the Ordinary shares of 4⅝ per cent. for the year under review. Last year, you will remember, we were able to pay 4⅞ per cent., or 6d. more than we propose to pay this year. When, however, we consider that the average dividend which this Company has paid since its formation in 1873 has been 4⅜ per cent., you will observe that our present dividend is above that average, and is, therefore, not discouraging; and if we take our Preference and Ordinary shares in like quantities they show a return of £5. 6s. 3d. per cent. I will now, gentlemen, refer more particularly to the dividends we have received from those companies which show increases or decreases as compared with last year. It will be seen, on reference to the report, that at the beginning of this financial year the amount brought forward was £936 less than the amount brought forward at the beginning of last year. The Brazilian Submarine Company has paid us £1,092 less than we received last year, this reduction being due to the fact that they have had to lower their rates in consequence of the competition which has existed from the South American Cable Company. Notwithstanding this reduction the return on those shares is 6½ per cent. for the year. The Telegraph Construction and Maintenance Company, I regret to say, gentlemen, has paid £2,188 less than they paid us last year. This is accounted for by two circumstances:—Firstly, the general depression which has existed in all departments of trade; and, secondly, the fact that during the year under review there have been no large orders executed by that Company. I may say, however, that the Chairman in his speech at the general meeting in February last stated that he hoped the reduction in the dividend paid would only be a temporary one. Still, the return on these shares, though less than last year, is £4. 19s. 9d. per cent. You are aware that the Telegraph Construction and Maintenance Company's dividend was a very large dividend; they paid 20 per cent., which is rather an unusual dividend in these times. They reduced it, however, to 15 per cent., but I believe they are now very full of business, although I am not very sanguine that they will revert to their 20 per cent. dividend for some considerable time. I think they will probably strengthen themselves in other ways, but, still, 15 per cent. is a dividend which I think most of you will consider a very fair and satisfactory one. The West African Telegraph Company, gentlemen, I regret to say, has not been able to make any return in the way of dividend during the past year. During the previous year they paid us £1,258, but this loss is looked upon as purely a temporary one, owing to the exceptionally heavy expenses which that Company has had to incur on account of the frequent interruptions to its cable off the mouth of the Congo. I may say here, for your information, that the West African Company has now taken steps to remove that cable from its former position, whereby it is fully anticipated that the cable will not be so liable to these interruptions which have proved so costly in the past. I may mention that this cable lay across the mouth of the Congo, and we have found from experience that these large rivers flowing into the sea have under-currents, of which we have all of late years been able to realise the power—the power which they have upon cables. We have therefore taken up that cable and relaid it 150 miles from the mouth of the Congo. The work is done, the cable is working satisfactorily, and I sincerely hope that we have got rid of the trouble and difficulty we have had at the mouth of the Congo. I may mention that during the year we have made three repairs in that cable, involving an outlay of £13,000, and if that amount had been in the exchequer instead, the West African Company would have paid a fair dividend. I hope that the next time I have the pleasure of meeting you I shall not have the misfortune of being obliged to say that we have received no dividend from that Company. We have also received a somewhat smaller dividend from the Western and Brazilian Company, namely £1,494, as against £2,391 last year, or a reduction of £897. This reduction, as in the case of the Brazilian Submarine Company, is partly due to the competition which has existed, to the depression in commercial affairs in South America, and the loss on Exchange. On the other hand, gentlemen, we have received a larger dividend from the Anglo-American Company, which shows an increase of £1,092 over the amount received from them last year. The dividends from this Company show a return of £2. 18s. 3d. per cent., as against £2. 16s. 1d. per cent. last year. We have received £1,025 more from the Submarine Cables Trust than they paid us last year. The investment under this heading shows a return of £6. 10s. 7d. per cent., as against £5. 1s. 6d. per cent. last year. We have also received a somewhat better return this year from the Western Union Telegraph Company, as compared with last year. We have received from this Company a certain amount of bonus shares during the year, and these have added to the value of our property. The returns on the other investments are practically the same as last year. It will be seen on reference to the report that we still receive large returns from some of the companies in which we have investments, notably, the Indo-European Company, the Eastern Extension Company, the Eastern Telegraph Company, and the Direct United States Company. I may say that during these very unsatisfactory times, probably the most unsatisfactory which have been experienced in London for a very long number of years, our submarine telegraph system, over which we have more or less control, has held itself probably in a higher and more satisfactory position for the shareholders than any other class of investment that has come under my notice. I hope that that state of things will continue. There is no doubt at all that during the depressed times telegrams come freely and frequently over our system. In lively times times business is good, and we have a similar experience then. At the same time where there is a general depression existing it affects us more or less in this way—that it interferes with what we call our legitimate trade traffic. The extra traffic that seems to come in dull times comes from sources which are less satisfactory than when they come from legitimate commercial transactions. The last time we met here Sir James Anderson was re-elected a Director. As you are aware, Sir James Anderson had been connected with telegraph enterprise for the last 25 years. He was always a zealous, hard-working man, and a man whose nautical experience—he had been a sea captain for many years of his life—made his services most valuable to the Company. He was a most satisfactory colleague to work with. He was always willing and ready to do his share of the work, and he was at the same time always sufficiently informed to impress his confidence upon his co-Directors. By his death we have lost a valued colleague and a very loyal man in his adhesion to the telegraph enterprise. His place, as you are aware, has been taken by the Hon. William St. John F. Brodrick, a Director of the Brazilian Submarine Company. As you are aware, this Company exists very much by its investments in submarine telegraph companies, and we try as far as possible to have a fair representation on our Board of the different companies. I have just mentioned about the hard times that we are passing through, and they are very hard

Digitized by Google

times indeed, but I remember the old-fashioned belief in regard to cycles of times. Cycles of bad times, it used to be said, are followed by cycles of good times. I hope that we have pretty well passed through the cycle of bad times, and that there is now a silver lining coming into view; and before we meet again I trust that we shall see a more healthy state of things than exists now. Still, I must caution you that there are circumstances and causes existing at the present time that have not come to the surface for a very long time past, and one in particular is the silver question. I am not going to discuss the silver question to-day, but I may mention that that question affects a great many of the companies in which we have investments, and to an extent which sometimes astonishes even people who are accustomed to deal in large figures. The loss in remitting money from these places to England is sometimes very serious indeed. We who are managing these companies endeavour to obviate the evil and reduce the loss as much as possible by increasing the rate, so as to make up for the loss, but even that does not always meet the expectations that we form, and it does not always recoup the loss which is sustained. However, I hope that that is passing away, and that with better times we shall also have an improvement in the position of they telegraph companies generally, and as they improve so shall we. It is interesting to mention, at a time like this, the general progress of telegraphy. As you are aware, telegraphs have nearly grasped the whole of the civilised world. There is scarcely a place where the British flag flies or where British influence and trade are exercised that telegraphs do not reach. A contract is just about to be completed by the Eastern Company with the Government for a cable to the Seychelles and Mauritius. That has been long talked about, and is very much wanted, and I believe now that within the next few months it will be completed. The Eastern Company have also made an arrangement with the Portuguese Government for carrying a cable to the Azores. This is a scheme which the French took an active interest in, and a year ago they actually had possession of the contract. But circumstances change rapidly in France, as you are all aware, and the result came about that the Government who had promised to support the French Company did not do so. The Government changed, and the result was that the French Company lost the contract, and we stepped in and secured it. We believed that we originally had the contract, but the French obtained it through offering terms which we did not consider prudent. However, we have now got it, and I hope that before the end of September the work will be completed by the Eastern Company. I think that is all the information that I have to give you. In regard to the position of submarine cables I may, however, say just one word more. The commerce of the world at the present time is being very largely conducted by telegraphy, supplemented, it is true, by the mails, but the origin and termination of business transactions are now almost invariably carried on by the telegraph. I hope that the commerce of the world will grow, and if so we may expect also to grow with it. The resolution which I have now to propose, gentlemen, is as follows:—

"*That the printed report and accounts for the year ended July* 18, 1893, *submitted to this meeting be, and the same are, hereby received and adopted, and that a dividend be now declared, payable on and after this day, of* 3*s. per share on the Preference shares, less income-tax, and of* 4*s. per share on the Ordinary shares (income-tax having already been deducted), making, with previous payments, a total dividend for the year of* 6 *per cent. on the Preference shares, less income-tax, and of* 4⅜ *per cent. net on the Ordinary shares of the Company.*"

The Marquis of TWEEDDALE seconded the motion.

Mr. WILLIAM GRIFFITH said that the Chairman's statement was so clear and satisfactory that there was nothing for the shareholders to inquire about. He desired, however, to testify—as he thought he might be allowed to do on the part of the shareholders generally—to the integrity, the skill, and the knowledge of telegraphy which the late Sir James Anderson displayed. It was gratifying to find that the place of the deceased gentleman had been filled so satisfactorily. They were all deeply interested in telegraphy, which was of essential importance to the commerce of the world, and he really thought that it did more good in the world generally than the Peace Society or the principle of arbitration.

The CHAIRMAN stated that the Directors, on their own behalf and on behalf of the shareholders, had already expressed their sympathy with the family of the late Sir James Anderson, but they would again convey to them the views which had been expressed by Mr. Griffith—feelings which he understood were unanimously shared in by all present.

The resolution was then carried unanimously.

On the motion of the CHAIRMAN, seconded by Lord SACKVILLE A. CECIL, Sir H. D. Gooch, Bart., was re-elected to his seat at the Board; as was also Mr. James Pender, on the motion of the CHAIRMAN, seconded by the Marquis of TWEEDDALE.

Mr. S. JOLLY then proposed, and Mr. FOSTER seconded, the re-election of the auditors, Mr. John G. Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths, and Co.), and Mr. William Griffith, and the motion was carried unanimously.

Mr. CARPENTER suggested that a column should be placed in the accounts showing the value of the different stocks held by the Company.

Sir H. D. GOOCH: They vary from day to day.

Mr. JOHN GRIFFITHS pointed out that it would be inexpedient and undesirable to act upon the suggestion of Mr. Carpenter.

The CHAIRMAN said that the Directors were very anxious to consider any suggestion which would give satisfaction to the shareholders, but the latter must not throw undue responsibility upon the Board. If they had had large investments—which, fortunately, they had not—in American securities, they would have seen a very great difference indeed in the prices that day compared with the prices 14 days ago.

Mr. CARPENTER said that of course the valuation should be taken on the day of the report, but the explanation of the auditor was quite sufficient, and if it was impolitic to give the information he desired that his suggestion might be considered withdrawn.

A cordial vote of thanks was then passed to the Chairman and the Directors for the satisfactory and efficient way in which the affairs of the Company had been administered.

The CHAIRMAN, in acknowledging "this oft repeated evidence of the shareholders' goodwill and confidence," remarked that it was a very great source of satisfaction to the Directors to be able—especially in times of financial disaster like the present—to show that their own affairs had been piloted so well through the sea of trouble. The position of the submarine telegraph enterprise stood high in the confidence of the shareholders, but he thought that those who were trusting to telegraphy in the present hard times were not in any way disappointed. Fortunes were, more or less, lost or won by prompt attention, and it was, therefore, a great fact to know that by means of submarine telegraphy London could communicate within a couple of hours with almost any part of the world. This was a great fact, and they could very well understand what an enormous boon it was, commercially, politically, and socially.

The proceedings then terminated.

Telegraph Construction and Maintenance Company (Limited).

In accordance with the resolution of the general meeting of February 28, 1871, a half-yearly general meeting of the Telegraph Construction and Maintenance Company (Limited), was held at 38, Old Broad-street, on Tuesday. Mr. Philip Rawson presided.

Mr. W. SHUTER (Managing Director) having read the notice calling the meeting, as above,

The CHAIRMAN said: You are probably all aware that at this meeting we have no figures to lay before you, or any resolution to propose, and therefore, as briefly as possible, I will lay before you a few points of interest with regard to what is going on in our Company. During the half-year that has just passed we have undertaken a contract for the laying of about 190 miles of cable on the West Coast of Africa joining up the Cameroons to Lagos. We have also entered into a contract with the Eastern and South African Company for the laying of a cable on the Eastern Coast of Africa from Zanzibar to the Seychelles and thence to Mauritius, a distance of about 2,300 miles. That, we hope, will be completed in the course of the present year. We have also obtained a concession for the laying of a cable from Lisbon to the Azores from the Portuguese Government, and that undertaking, I believe and hope, will be completed in the course of a month or two from this date. These are the principal contracts we have entered into and the chief amount of work in hand. The whole affair involves a manufacture of about 3,500 to 4,000 miles, about 2,300 of which are already completed. The general business of the Company has remained in a satisfactory condition during the past half-year, and the business at the gutta-percha works is somewhat in excess of what it has been in any previous year. I think when I have said that I have said all that is of any interest to you, but I shall be happy to answer any question you may wish to ask. I have no resolution to propose.

Mr. SYKES inquired whether the shareholders were justified in hoping from the statement just made by the Chairman that the final dividend for this year would be an improvement on the last.

The CHAIRMAN: That is a very difficult question to answer; indeed, it is almost impossible to answer it. Hitherto all the contracts we have undertaken we have carried out without any mishap; but it is impossible to say that an accident will not occur in the laying of any one of these cables, and in the event of an accident it might be very prejudicial. I hope and trust that no such accident will take place, but it is impossible to forecast the profit we may derive beforehand from any one of these undertakings. On the whole, the business of the Company is going on favourably, but I should not like to commit myself to any figures. I feel it would be an improper thing to do at the present time.

Mr. SYKES said he had asked the question because the final dividend of last year was so exceedingly disappointing, and he thought it was the general opinion of the shareholders that the explanation given to account for it was very meagre. Of course, he was aware that in case of an accident happening it would be impossible to answer the question which he had put. What he had meant to ask was whether, barring accidents, they might hope for an improved dividend over that of last year.

The CHAIRMAN: I must say that I should not like to commit myself to any prophecy. The business of the Company is going on prosperously and well, I hope, and I trust that there may be no disappointment; but I commit myself to no statement. Unfortunately, I was not present on the last occasion, being very ill at home, and I do not know what took place. Therefore, when you say that the explanations given on that occasion were inadequate, I am sorry that I am unable to add to them.

Mr. BOYD asked how the work in hand now compared with that which they had last year.

The CHAIRMAN: As far as I remember, we are doing more work this year than we were last year.

Mr. BAYFORD said that theirs was an old-established Company, and he thought it would be desirable if the Board could give the shareholders a little more explanation. There had been, owing to circumstances which, he had no doubt, were perfectly natural and explicable, a fall in the value of the shares and in the amount of the dividend. If the Directors could give the shareholders some information on this point he certainly thought it would be well.

Mr. SYKES said that the dividend last year was a third of what it was in the previous year.

A SHAREHOLDER: No, no.

A SHAREHOLDER: You mean one-third less than in the year before.

The CHAIRMAN: No, it was one-fourth less; it was 15 per cent. We have been paying for many years past 20 per cent., and have had an extra-

Digitized by Google

ordinary run of prosperity. One year comes, and we are not able to keep up the old dividend, but that is a very natural thing to have happened, and the wonder is that it did not occur before. I should think you would find very few companies with such a record as ours. I cannot add anything to what I have said. We must hope and trust in the future, and I hope that you will not be disappointed when we declare the final dividend.

Mr. BAYFORD observed that the dividend was a very good one; but there was a falling-off in it, and that arose from increased competition or increased cost of work. Surely they might have an explanation on such a point as that. If the Chairman could say that it was not desirable in the interests of the Company that these questions should be answered he would not press them any more; but he thought there might be some little indication given as to how it was that, although they were in a very prosperous condition, they were not in such a prosperous condition as before.

The CHAIRMAN: I have told you that we are more prosperous now than we were last year. We are doing an increased business, but what the final result will be I cannot tell.

A SHAREHOLDER: You are doing more work?

The CHAIRMAN: We are doing a great deal more work than we were a year ago.

A SHAREHOLDER: At as good a price?

The CHAIRMAN: Yes, I should say at as good a price.

The Rev. E. HAWKIN asked whether the decline in the dividend last year was owing to a diminution of work or to an increase in the cost.

The CHAIRMAN: As I have said, I was not present at the last meeting, but I believe the matter was explained. It was owing to a diminution of work, and at the same time lower prices. In other words, there was less work to do and more competition, with the natural result.

A SHAREHOLDER asked whether the interim dividend was going to be paid, as usual.

The CHAIRMAN: Yes, it will be posted to-night. I ought to have mentioned that, and I am glad you have done so.

The proceedings then terminated.

Chili Telephone Company (Limited).

The following is the report of the Directors of this Company for the year ended March 31st last. The shareholders' meeting takes place at Winchester House, E.C., on Wednesday, August 2nd, at 12:30 o'clock.

The business of the Company during the past year has shown a satisfactory improvement in dollars, but has been less profitable in sterling than that of previous years. This result is due to the depreciation in the sterling value of the dollar, which has fallen from 19d. on March, 31, 1892, to 15d. on the same date this year. The income in dollars from subscribers and other sources for the year ended 1892-3 was $448,661, and for the previous year, $378,830, showing an increase of $69,831. The maintenance, operating, and general expenses in Chili were, in 1891-2, $271,180, and in 1892-3, $263,988, or a reduction of $7,192. The increase of income having been $69,831, and the diminution of expenses $7,192, the total result was more favourable than in 1891-2 by $77,023. The outgoings in 1891-2 were 71·6 per cent. upon the gross revenue, but in 1892-3 they fell to 58·8 per cent., a reduction of nearly 13 per cent. This satisfactory increase of profit was in dollars only; the unfavourable rates of exchange reduced the available income in sterling very considerably: The net profit on working was in 1892-3, at 18d. the dollar, £13,850; and in 1891-2, at 19½d. the dollar, £3,746; showing an increase, notwithstanding the fall of 1½d. in the average value of the dollar, of £5,104; but the loss on the sterling value of the liquid assets on March 31st, comparing the same two years, was 4d. per dollar, and amounted to £4,750, and that therefore the net increase in sterling was only £354. The increase in the outgoings in England—including the interest on debentures—was £1,027, so that the net available sum for the year is less by £673 than in the previous year.

The profits having been used for capital purposes cannot be divided, and consequently the balance has been carried to a reserve account. As the tariff rates are paid in the paper dollar—now so seriously depreciated—the Board has found it imperative to increase those rates. This has been done in some centres, and will be done in others. A reduction in the number of subscribers may therefore be expected, but the income will doubtless be maintained throughout, and probably considerably augmented, when the irritation generally created by changes of this kind may exhaust itself.

It will be observed that the capital outlay for the past year is £16,701, being £2,000 less than the previous year. This sum has been expended on the completion of the construction of the new trunk lines, and the usual preparation for connecting additional subscribers with the exchanges, the latter is now the only kind of expenditure on capital account. The 4,000 shares offered to the proprietors were all taken by them, and have all been paid for in full.

Messrs. Allsopp and Greenwood retire from the Board of Directors, and being eligible, offer themselves for re-election. The Auditor, Mr. Thomas A. Welton, also retires, and offers himself for re-election.

City and South London Railway Company.

The following is the report of the Directors, to be submitted to the half-yearly ordinary general meeting, to be held at Winchester House, E.C., on Tuesday, August 1st, at 12 o'clock noon:—

The receipts from all sources for the past half-year have amounted to £23,159. 6s. 3d., and the cost of working has been £14,964. 0s. 6d., leaving a profit of £8,195. 5s. 9d. Inclusive of the balance brought forward from December 31st last, the net revenue account shows an aggregate total of £9,073. 12s. 10d. After making provision for the debenture and debenture stock interest, amounting to £4,110. 13s. 10d., a balance remains available for dividend of £4,962. 19s. Out of this sum the Directors recommend the full dividend of 5 per cent. per annum be paid on the Preference shares, and that a dividend at the rate of ¾ per cent. per annum be paid upon the Consolidated Ordinary stock, leaving a balance of £898 to be carried forward to the next account.

The number of passengers conveyed during the six months ended June 30, 1893, exclusive of season ticket holders, was 3,146,656, showing an increase over the corresponding period of the previous year of 333,494. This increased traffic has been carried with immunity from any accident whatever, and the train service has been worked with unfailing regularity.

The Directors regret that the amount paid for local rates and taxes continues to show an increase.

The following table shows the number of passengers, exclusive of season ticket holders, carried since the opening of the railway in each half-year:—

Half-year.	Number of Passengers.	Receipts (including season tickets).
Ended December 31, 1890 (11 days) about	165,000	£1,568 3 9

The engineer certifies that the locomotives, rolling stock, generating plant, permanent way, and station buildings, have been efficiently maintained in good working condition. The new sidings at the Stockwell terminus are nearly completed, and will shortly be brought into use. The working of the traffic will be greatly facilitated by this much needed accommodation. To meet the requirements of the increasing traffic, some additional rolling stock is now in course of construction.

The Bill for the extension to Islington and other purposes has passed the House of Commons, and now awaits the Committee of the House of Lords, where it is unopposed. This Bill includes also the extension of time for the purchase of lands and construction of works under the Act of 1890 (Clapham Extension).

During the half-year £3,800 of terminable 5 per cent. Debenture Mortgage Bonds have been paid off and replaced by 4 per cent. Perpetual Debenture Stock. In order to provide at once some additional accommodation for passengers at the entrance to the King William-street station, the lease of the adjoining premises in Arthur-street East has been acquired on favourable terms, and the requisite alterations will shortly be commenced.

Liverpool Overhead Railway Company (Limited).

The Directors' report states that, owing to the delay in completing the electric signalling, only a ten minutes' service could be worked until May 22nd, since which date a five minutes' service has been established. They have pleasure in reporting that the main structure of the line has been completed, and that the electrical equipment has been working satisfactorily, the traffic being conducted with great regularity. The total number of passengers carried is 1,370,742, of which number 235,487 were first class, 956,922 second class, and 178,333 travelled with the cheap workmen's return tickets, which the Company have recently issued. A contract has been entered into with Messrs. Holme and King, of Liverpool for the extension of the railway to Crosby-road, Seaforth, from which considerable additional traffic is expected. The Directors have decided to ask the shareholders for authority to issue the remaining Preference capital of £45,000, but they do not anticipate that more than one-half will be required to provide funds for completion of the northern extension and for working capital. The accounts for the period during which the railway has been at work show that the gross receipts have been £12,352. 0s. 2d., and the working expenses £6,990. 5s. 2d., leaving a balance carried to net revenue account of £5,361. 15s. After providing £1,623. 5s. 11d. for interest on mortgage debentures from March 6th, and £122. 16s. 9d. for interest on calls paid in advance, &c., the balance available for dividend amounts to £3,644. 16s. 4d., out of which the Directors recommend a dividend of 5 per cent. per annum upon the Preference shares, which will absorb £351. 7s. 4d., leaving a balance of £3,293. 9s. to carry forward to next half-year.

Edison and Swan United Electric Light Company (Limited).

The following is the report of the Directors to be presented at the tenth annual meeting, to be held at the Cannon-street Hotel to-day (Friday), at 1 p.m.:—

The business of the Company for the year ended June 30, 1893, has resulted in a credit balance of £86,642. 5s. 1d. Of this £20,632. 19s. 5d. was distributed on March 14th last, as an interim payment on the "A" shares. The Directors recommend a further distribution of £22,976. 1s. 5d. on the "A" shares; and the whole of the cumulative Preference on the "A" shares having now been paid, of £3,534. 12s. on the "B" shares, the whole to be distributed accordance with the provisions of Clause 87

Digitized by Google

of the Articles of Association. This will absorb £47,143. 12s. 10d., leaving £39,498. 12s. 3d., which the Directors have carried to the reserve fund, in accordance with Clause 89 of the Articles of Association. This will make the present distribution :—On the Ordinary "A" shares, 4s. 1d. per share ; on the fully-paid "A" shares allotted to the Swan United Company, 5s. 1d. per share ; on the fully-paid "A" shares allotted to the Edison Company, 6s. 8¾d. per share ; on the "B" shares (fully paid), 3s.—all free of income tax.

The Directors are developing the manufacturing branch of the business, and are making and supplying electrical instruments, fittings, and electrical appliances. They have re-opened the factory at Newcastle, and have opened depots for the sale of lamps and fittings in the principal towns in the provinces.

Major Flood Page and Mr. S. Bidwell, F.R.S., retire by rotation from the Board, and offer themselves for re-election. Messrs. Welton, Jones, and Co., the auditors, also offer themselves for re-election.

Crompton and Co (Limited).

The fifth report of the Directors of this Company for the year ended March 31st last, to be presented at the annual general meeting of the shareholders at the Cannon-street Hotel, E.C., on Monday, the 31st inst., at 3 o'clock, is issued, and is as follows :—

The accounts show that although the gross profits gives an increase upon the figures of the preceding year, the net results have been adversely affected by unusual and unforeseen expenditure. In January last the boilers at the Chelmsford Works suddenly gave out, and had to be replaced by others, and the year's working has had to bear a large share of the cost of this renewal and of the temporary arrangements necessitated thereby. It is highly improbable that any similar abnormal expenditure will recur in future years, but the Directors feel confident the shareholders will agree with them that it is right it should be charged to the year's account, even at the cost of a reduced dividend.

The orders in hand continue good, and negotiations for several important contracts are approaching completion.

The net profits for the year amount to £11,953. 7s. 4d., and after providing for debenture interest and payments set out in the revenue accounts, and deducting the interim dividends paid, there remains, with the £98. 10s. 2d. brought forward from last year, a balance available for dividend of £3,019. 12s. 8d. The Directors propose, after setting aside £750 as a provision for doubtful debts and contingencies, to declare a Preference dividend of 2s. 6d. per share, making, with the interim dividend already paid, 6 per cent. per annum on the Preference shares, to provide which the sum of £800 will be taken from the reserve fund.

Mr. H. H. J. W. Drummond retires from the Board of Directors by rotation, and offers himself for re-election, as do the auditors, Messrs. J. H. Duncan and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

DISTRICT MESSENGER COMPANY OF PARIS (LIMITED).—This Company was registered on the 22nd inst., with a capital of £200,000, divided into 80,000 Ordinary and 112,000 £7 per cent. Preference shares of £1 each, and 400 Founders' shares of £20 each, to adopt and carry into effect the agreement with Charles T. Russell, to engage and provide messengers, commissionaires, porters, and watchers, in connection with a system of electric call boxes, and to generate, purchase, supply, and apply electricity for any purpose.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—This Company was registered on the 20th inst., with a capital of £400,000, in £2 shares, of which 50,000 are Preference shares and the remainder Ordinary, to acquire and take over as a going concern the business, goodwill, and assets of the Electric Construction Corporation (Limited), to carry on and develop the said business, to enter into such arrangements as the Board may consider necessary for the taking over of the said concern, and to carry on in all or any of its branches the business of electrical and mechanical engineers, electricians, suppliers of electricity for the purposes of light, heat, sound, motion, force, &c., and manufacturers of, and dealers in, electrical appliances generally. The subscribers are :—

	Shares.
Sir Daniel Cooper, Bart., G.C.M.G., 6, De Vere-gardens, S.W.	1
Rt. Hon. David Plunket, Q.C., M.P., 12, Mandeville-place, W.	1
Emile Garcke, Queen-street-chambers, E.C.	1
Sir Henry C. Mance, C.I.E., Manora, Bedford	1
Thomas Parker, M.I.C.E, Newbridge, Wolverhampton	1
P. E. Beachcroft, 112, Portsdown-road, Maida Vale, W.	1
J. W. Barclay, 5, Clarendon-place, Hyde Park-gardens, W.	1

The first Directors are :—Sir Daniel Cooper, Bart., G.C.M.G., Sir Henry C. Mance, C.I.E., the Right Hon. David Plunket, Q.C., M.P., James W. Barclay, Philip E. Beachcroft, J. Irving Courtenay, James Pender, and Emile Garcke.

RUGBY SCHOOL ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on the 24th inst. with a capital of £5,500, divided into 110 shares of £50 each, to carry on at Rugby the business of an electric lighting company in all its branches, and to supply electricity for the lighting of the boarding houses and buildings connected with the Rugby School, as are occupied by persons holding an appointment in the school, or in connection therewith.

EASTBOURNE ELECTRIC LIGHT COMPANY (LIMITED).—The annual return, filed on May 19, 1893, shows that 1,017 Ordinary and 40 Preferred shares were subscribed for out of a total capital of £50,000, in £10 shares. Upon these shares the full amount has been called, and £10,570 paid.

EASTON AND ANDERSON (LIMITED).—The annual return of this Company, made up to May 13th, has been filed. The nominal capital is £250,000, divided into 2,060 Ordinary and 440 £5 per Cent. Preference shares of £100 each. All the Ordinary and 184 of the Preference shares have been taken up, of which the former were issued as fully paid. The full amounts have been called, and £18,400 paid on the Preference shares.

ELECTRICAL STANDARDISING, TESTING, AND TRAINING INSTITUTION (LIMITED).—In reply to official inquiries as to whether this Company should remain on the list of joint-stock concerns, Mr. P. A. Latham, of 15, St. Helen's-place, Bishopsgate-street, London, E.C., states that no issue of shares has been made, and that it is the wish of the seven signatories, who are the only shareholders, that the name of the Institution should be erased from the joint-stock register.

EVERED AND CO. (LIMITED).—The annual return of this Company, made up to April 13th, has been filed. Out of a nominal capital of £200,000, in £10 shares, 16,496 shares have been taken up. The full amount has been called on 6,744 shares, while a call of £7 per share has been made on the remaining 9,752 shares. The calls paid amount to £135,704.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 23rd were £761, as against £783 for the corresponding period of last year, being a decrease of £27. The total receipts for the half-year amount to £2,603, against £2,286 in the corresponding period of 1892, being an increase of £317.

CHARING CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of £5 per cent. per annum on the Ordinary shares (30,000 of £5 each), which will be paid on August 15th.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The Directors have decided, subject to audit, to recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum (free of income-tax) on the Ordinary shares ; both for the half-year ended June 30th last.

DISTRICT MESSENGER COMPANY OF PARIS (LIMITED).—The prospectus of this Company has been issued during the week. It is proposed to introduce the electric call system into France by organising a parent company to establish the system in Paris, and by then organising subsidiary companies for other towns. The capital of this Company, which is to acquire nearly the whole of the shares of the recently formed Parisian Company, is £200,000, in 12,000 £7 per cent. Preference and 80,000 Ordinary shares of £1 each, and 400 Founders' shares of £20 each, £30,000 of which (the prospectus states) has been already subscribed in Paris. The capital of the Company seems ridiculously large.

DUBLIN UNITED TRAMWAYS COMPANY.—The half-yearly meeting of this Company was held last week in Dublin, when the Chairman, in reply to a question as to whether some other motive-power could not be substituted for horses, said that there was a Bill before Parliament, which had every prospect of passing, for using electricity on the line between Dublin and Dalkey. It would not be on their line, but on the Southern District line. If the Bill were passed, and the result proved satisfactory, he was sure that it would show the Corporation that they ought to give their Company facilities to do the same thing, and on their part, they would be quite prepared when the time came, and when a generating station appeared to them to be properly working to adopt electricity.

ELECTRICAL ENGINEERING CORPORATION (LIMITED).—A meeting will be held at 58, Coleman-street, E.C., on August 22nd, at 12, to receive the liquidator's account of the winding-up.

MADRAS ELECTRIC TRAMWAYS COMPANY (LIMITED).—We mentioned in a recent number that this Company had been unsuccessful in obtaining an extension of time in which to obtain further capital, and that the concession had been cancelled The solicitors to the Company have made another appeal to the Municipal Commissioners and to the Government for an extension of six months in which to obtain a *bonâ fide* subscription of £75,000, failing which the solicitors admit that the shareholders would have no reasonable cause of complaint if the concession were cancelled.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).—The Directors of this Company have resolved to recommend to the shareholders, subject to final audit of the accounts, a dividend for the year ending December 31st last at the rate of 2½ per cent. on the entire paid-up capital of the Company. The dividend being payable only to the holders of the Ordinary shares, is equivalent to £3. 12s. 2d. per cent. on each share of 11s. paid, the same rate as paid for the previous year.

Digitized by Google

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The Directors of this Corporation have declared an interim dividend for the half-year ended June 30th last at the rate of 3 per cent. per annum, payable on September 1st next to shareholders on the register on July 26th.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 21, 1893, after deducting 17½ per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,337.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 794.—Vol. XXXI. FRIDAY, AUGUST 4, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The accounts of the Glasgow municipal electric lighting station for the first fifteen months of its existence show a loss of £1,773. The total outgoings between March 1, 1892, and May 31, 1893, amounted to £6,741, including £1,328 for depreciation, whilst the total incomings were £7,781. As, however, £2,812 has to be set aside for payment of interest on loans and redemption of capital, the apparent profit of £1,039 is converted into the above-mentioned deficit. With judicious management the operations of the next twelve month should result in, at least, an equilibrium.

We are glad to learn from a statement made by Mr. Mott at Tuesday's meeting of the shareholders of the City and South London Railway Company that the lighting of the carriages is engaging his attention, since we cannot but re-echo the remark of one of the shareholders that "it would be well if the lighting of the carriages could be somewhat improved." "A dim religious light" is all very well if it is steady and accompanied by "storied windows richly dight," but it is a nuisance when it is of an oscillatory character and its locus is a crowded car which is being shot through a dark tube. The semi-annual allusion to the "pure atmosphere, free from all noxious vapours," and the "even temperature, which is pleasant both in summer and winter" might also be taken as said until the facts and the epithets agree a little more closely. The atmosphere on the City and South London line is, of course, a decided improvement upon that which does duty on the Underground, but its purity and pleasantness are open to question. There is, we know, "some soul of goodness in things evil would men observingly distil it out," and even the so-called air on the Underground is, the Chairman of that railway assures us, conducive to longevity; but no amount of reiterated assertion will make the general public take kindly to either atmosphere.

The chief feature in connection with the Andreoli Ozoniser which we have had the opportunity of inspecting at Messrs. Allen and Hanbury's works is that there is very free circulation, so that a large volume of air is acted upon with free diffusion of the ozone as it is formed, and the ozonisation does not take place in a confined space as in most types of ozonisers. A very high efficiency in the proportion of ozone formed from atmospheric air is claimed by Mr. Andreoli, and from the construction of the apparatus one would expect this to be the case. Information is, however, wanting on the all-important question of the cost of production. That ozone is best produced by the silent discharge, and that a certain proportion of ozone in the air is beneficial to health, are two pretty well established facts, but the step from these two premises to the conclusion that the electrical production of ozone is synonimous with the cheap and efficient disinfection of our slums is not one which we are prepared to take on the evidence before us. What is required is a test made, say, on the air exhausted from the Brompton Hospital, where the volume of air treated, its composition before and after, and last, but not least, the cost of treatment, could be accurately tested.

There is a theoretical and there is a practical side to the researches of Dr. Duncan and his colleagues on the behaviour of the electric arc under pressure, which we publish this week. From a theoretical point of view the experiments are a step forward towards the solution of the vexed question as to the distribution of potential in the electric arc. There are two assumptions possible: that the distribution is entirely due to "ohmic" resistance of the carbon vapour, the specific properties of the vapour depending on the current density, and varying in a complex manner; or, that the distribution is split into a portion due to a counter electromotive force, and a remainder which is due to the resistance of a vapour the specific resistance of which is independent of the variations in the conditions of the arc, or which varies in a different manner from that required under the first assumption. Assuming the existence of this counter electromotive force, the experimenters have endeavoured to produce a series of conditions by which its elements could be determined; and they show grounds for believing that these elements consist in a large electromotive force due to carbon vapourisation, and a small electromotive force due to the thermo-electric effects of two carbon-carbon-vapour couples at different temperatures; both these elements being functions of the current and length of arc.

From the practical point of view, these experiments tend to confirm a suggestion which was made by Mr. E. T. Carter during the discussion which took place at the Institution of Electrical Engineers, in April, 1892, on "Notes on the Light of the Electric Arc." It was pointed out that the fact of placing the arc under increased pressure (not voltage) must increase the temperature and efficiency of the arc, as well as cause more light to be emitted from a given size of carbon. The curves

Digitized by Google

given in Fig. 3 of Dr. DUNCAN'S Paper show that between 1 and 10 atmospheres there is a very considerable difference in the voltage at which a given current is maintained in the arc, and indicates that the candle-power and efficiency of the light would rise with the pressure. It will be seen, therefore, that the carbon-economising plan of running an arc *in vacuo*, which is favoured so much by certain inventors, would result in increasing the watts per candle owing to the low temperature the arc would have.

THE argument by which M. RICCARDO ARNÒ arrives at the conclusion, which will be found in our columns this week, that ebonite exerts a selective diathermancy which increases with the frequency of the radiation wave, is one which appears to be faultlessly logical; and the conclusion itself is not unimportant. By a series of well graduated experiments, in which the proportion of high-frequency waves is gradually reduced, a smaller and smaller percentage of energy is found to be transmitted through the sheet of ebonite; and this, apparently independently of the degree of polish and thickness of the material. It is not so easy, however, to discover from M. ARNÒ's investigations, what is the precise relation between a polished and an unpolished slab. M. ARNÒ has omitted to experiment upon slabs of equal thickness under these two conditions; and it is with some hesitation that we infer from the experiments he actually did make, that the polished state makes little or no difference to the relative diathermancy of different thicknesses. The point is well worth special investigation. In this connection it is interesting to notice the results of some researches on the transmission spectra of certain substances in the infra-red, by Prof. E. F. NICHOLS, which we find in the recent first number of the *Physical Review*. Comparing the diathermancy of plate glass with that of ebonite, when a series of wave-lengths in the infra-red were employed, the two curves of percentage transmission are, within the limits of probable error, found to be practically parallel.

IN DR. OLIVER LODGE'S letter last week he suggested that it was just possible that a universal medium which resists the motion of matter through it might really exist; but to avoid misapprehension, he now explains that he by no means implies that he believes in it as an actuality, and has good reasons for believing that etherial viscosity is really *nil*. It is a pity, after starting so interesting a discussion on Mr. OLIVER HEAVISIDE'S article, that the hypothesis of the two compensating forces should be so hastily withdrawn. The first point suggested by Mr. LARDEN in his letter to us this week has been already noticed in our last leading article. We there pointed out that, under the conditions suggested by Dr. LODGE, it appears that there would be an aberration moment on the sun. The energy dissipated by the motion of the planet through the viscous medium would *ex hypothesi* fail to retard this motion, and the only other source is the energy of the sun, or of the system. The effect of the curvature of the line of force, alluded to by Mr. HEAVISIDE this week, would be to reduce the rotational energy of the sun, or to set up perturbations which would reduce the total energy of the system.

MR. CONRAD COOKE'S letter to *The Times*, which will be found reprinted in our Notes, is but another instance of the lamentable muddle at Chicago. Mr. CONRAD COOKE'S intimate acquaintance with exhibitions, and his previous experience as juror, might have been of great service, but the Chicago Exhibition is, we fear, past saving. Two other gentlemen who have accepted nominations as jurymen have, we understand, not made a move westwards as yet. It might be rude to suggest that they are waiting for their fees before they start; perhaps they are only less enthusiastic about exhibitions than their unfortunate *confrère*.

Manchester.—The municipal electric lighting station was formally opened on Tuesday.

Hull.—The Local Government Board has sanctioned the borrowing of £10,000 for the purposes of electric lighting.

The Forthcoming Electrical Congress at Chicago.—Major-General Webber informs us that he has been appointed a delegate to the Electrical Congress at Chicago.

Fire at the Lyons Telephone Exchange.—The central telephone exchange at Lyons took fire on Saturday night. It was found necessary to cut the whole of the 1,250 connecting wires, and the telephone service of the city will consequently be interrupted for some time.

University College, Liverpool.—The 1893-94 session of this College commences on October 2nd. Complete courses of Instruction are arranged in (1) Civil Engineering; (2) Mechanical Engineering; (3) Electrical Engineering. For further particulars see our advertisement columns.

Institution of Electrical Engineers.—Among the Papers to be read during the next Session will be one on "The Electrical Transmission and Distribution of Power at Niagara Falls," by Prof. George Forbes; and one, "The Electric Lighting of the City of London," which has been promised by Sir David Salomons.

Electrical Bills in Parliament.—The Blackpool, St. Anne's and Lytham Tramways, and the Hampstead and St. Pancras and Charing Cross Railway Bills have passed Lord Morley's Committee of the House of Lords, the former having the "modified model clauses" inserted in it. On Monday the City and South London Railway, and the Barry Railway Bills were read a third time in the House of Lords.

Cement for Steam Pipes.—An American contemporary recommends the following recipe for a cement for stopping up leaky steam-pipe joints: five parts of plaster of Paris, five parts of yellow ochre, ten parts of litharge, five parts of red lead, and four parts of black oxide of manganese. These powders are mixed thoroughly, and a small amount of asbestos powder and boiled oil added. The cement will harden in from two to five hours.

Personal.—Mr. George A. Spratt has arrived at Gibraltar to take over the duties of superintendent at the Eastern Telegraph Company's quarters, vacant by the decease of Mr. De Sauty. Mr. Carey, for some time electrician on the cable ship John Pender, has also arrived, and acts as assistant-superintendent at the Gibraltar Station in place of Mr. F. Taylor, who left Gibraltar on Friday last for England, to relieve Mr. Spratt at the Company's Porthcurnow establishment.

Owen's College, Manchester.—The prize for the best essay on the Technical Applications of Electricity, has been awarded to Mr. J. R. Ashworth. This prize, of the value of £10, was given in the present year by Dr. Edward Hopkinson, the subject of the essay being "The Testing of the Efficiency of Dynamos and Motors."—The autumn session of this College commences on October 3rd. A special course on the technical applications of electricity has been arranged. Further particulars will be found in our advertisement columns.

Communication with Lightships.—In the House of Commons last week, Mr. Penrose Fitzgerald asked what steps had been taken to connect by telegraphic or telephonic communication

Digitized by Google

with the shore any of the lightships, as recommended by the Royal Commission on December 8, 1892. Mr. Mundella stated that orders had been given to prepare the Kentish Knock Lightship for the reception of the cable without delay. The recommendations of the Commissioners were not being disregarded, but the Board of Trade were dealing with one case at a time.

Measuring the Efficiency of Transformers by their Heating. This workshop method, to which Mr. Mordey first called attention in his Paper on "Alternate Current Working," read before the Institution of Electrical Engineers in May, 1889, has been rediscovered by M. G. Claude, who describes it in *L'Industrie Electrique* for July 25. The difference is that whilst Mr. Mordey lays his thermometer directly on the iron, and covers it by a packing of cotton waste, M. Claude places his thermometer in the surrounding oil, thus restricting the method to oil transformers as well as to small transformers, but making it less liable to error.

The Government and the National Telephone Company.—In answer to a question put in the House of Commons on Monday night, Mr. Arnold Morley stated that an agreement to give effect to the policy decided upon by the Telegraph Act, 1892, and the Treasury Minute of May 23rd of that year, was in course of settlement with the National Telephone Company. In pursuance of the recommendations of the Select Committee, to which the Bill was referred, the agreement would be laid before Parliament, but the Committee were of opinion that the reponsibility for the details of the agreement should rest with the Government, and he did not propose, therefore, to lay it upon the table of the House before it was signed.

Hamburg.—The contract for the extension of the Hamburg electric light station and the distribution of electrical energy over the whole town has been given to Messrs. Schuckert and Co., of Nuremberg. Some 300 H.P. of the electric energy produced at the central station will be used for some tramway lines in the town. If this experiment proves satisfactory all the tramways of the town, requiring about 1,000 H.P., will be driven by electricity. It is also intended to connect the central railway station, which is in course of construction and which will require a large amount of current for light and power, with the central lighting station. Another 500 H.P. has to be provided for the cranes, which have been and will be erected in the harbour.

The City and Guilds of London Institute.—At a meeting of the Council, held on the 31st ult., the diploma of "Associate of the City and Guilds Institute" was awarded to the following third year students of the Central Institution:—Civil and Mechanical Engineering: K. W. Digby, G. A. Fry, G. H. Heelas, R. F. Krall, H. F. Robinson, A. E. H. Sonneborn, C. V. Drysdale, T. L. D. Hadwen, E. L. Joselin, H. C. Leake, R. D. T. Roe, and W. T. W. Sussman. Physics and Electrical Engineering: G. H. Ballie, W. A. Brodie, W. Casson, J. R. Dick, A. H. Finlay, E. E. Gunter, W. E. Miller, J. Barnard, R. B. Burrowes, W. R. Cooper, W. H. Everett, E. G. Fleming, T. Hemmant, N. Ward, and C. H. C. Woodhouse. Applied Chemistry: O. F. Russell.

Electric Heating.—It may be interesting to our readers to note that in carrying out the new method of electric heating discovered by Prof. Lagrange and M. Paul Hoho (see *The Electrician*, Vol. XXX., March 31st, p. 622) some care must be exercised in the method of working the switch. In a communication to the *Electrical World*, Mr. Jules Neher says that he has found it to be important to close the switch *before* immersing the metal rod, which forms the kathode, in the acidulated water. When this is done the hydrogen separates the metal from the liquid, and the arc which is produced across the gap heats the metal to whiteness; but if the switch is closed only after the metal is immersed, no arc is formed, and the current is expended merely in electrolysing the water.

Electric Lighting of the Halifax Flour Society's Mill.—At the last half-yearly meeting of the Halifax Flour Society the Secretary gave some information as to the saving the Society had effected by adopting the electric light. For 1892, he said, their total payments for gas and the electric lighting amounted to £122. 5s. 8d. In 1890, when they had no electric light, their gas account was £174. 0s. 1d. There was thus a difference of about £52. That, however, was not all, as, by putting in the electric light they effected a saving of their insurance of between £60 and £70 per annum. The Secretary added, that the figures were all the more significant when they took into consideration that, two years ago, they ground 100,048 quarters, and last year 127,150 quarters. The use of gas, he said, was now almost confined to their stables.

The Telephone Question at Manchester.—A Sub-Committee of the Highways Committee has just concluded a report on the subject of telephone wayleaves and wires. Having inspected the Sheffield underground system, and taking into consideration the objections entertained by the City Council to overhead wires, the Sub-Committee feel justified in recommending that facilities upon a fair basis and under proper conditions should be granted by the Corporation to telephone companies to place their wires underground. For the facilities thus accorded, it is suggested that the Corporation should make on the Company an annual charge in respect of each subscriber to the Manchester Telephone Exchange or Exchanges to the extent of 5s. per subscriber. The annual sum which the Corporation would receive at the present time upon this basis would amount to about £400.

Royal Societies Club.—A club with this title is about to be formed "at the suggestion of many gentlemen of influence and to meet an obvious want." The membership will be limited to Presidents, Members of Council, Fellows and Members of the principal Royal and Learned Societies of the British Empire, Academicians and Associates of the Royal Academies, together with the Presidents, Members of Convocation, Council and Professors of the Universities and various Royal Institutions. Premises have been secured at 63, St. James'-street. The present terms of subscription are six guineas for town members, three guineas for country members, and two guineas for foreign and colonial members. Amongst the founders of the Club are Sir David Salomons, Sir Frederick Abel, Sir John Pender, and Prof. Andrew Jamieson. The Club will be opened in October. Its temporary offices are at 3, Waterloo Place, Pall Mall.

The Reckoning.—"Men laugh and riot till the feast is o'er; then comes the reckoning, and—they laugh no more." The truth of this adage has dawned on our colonists in Australia, to the chagrin of, among many others, the Professors of Melbourne University. Regardless of the warning cries of political economists and financiers of experience, the Colonies have for many years persisted in a course of reckless and unproductive expenditure. Now bank after bank has been putting up the shutters, general depression reigns; and the University of Melbourne has been one of the scapegoats to the tune of £5,000 last year and an additional £3,000 this year deducted from the Government grant. The Professors have interviewed the Premier on the subject; and it is to be hoped that the course of technical education, which has just got a fair footing in the colonial Universities, will not be injured by such stringent measures.

The Blackening of Incandescent Lamp Bulbs.—The deterioration of incandescant lamps has often been prettily described as being due to a "bombardment" of electrified carbon molecules, but Prof. Elihu Thomson holds that in a well-exhausted lamp it is due almost entirely to prosaic evaporation. He assumes, of course, that the vacuum is so good that no visible discharge of electricity takes place, which would, naturally, wear out the filament by actual carriage of carbon. He thinks that it would be very strange if carbon maintained at so high a temperature in a vacuum did not evaporate. In a lamp a certain evaporation takes place which is independent of the size of the bulb, from which it follows that the coating will become much less as the bulb is greater in size, for the same deposit will yield a much thinner coating of carbon over a large surface than over a small one. If one lamp were made with the smallest possible bulb and another with a large bulb, the former might be rendered opaque, while the latter would only be slightly darkened, other conditions being the same.

Lightning.—During a thunderstorm last week Cherkley Court, on Leatherhead Downs, was struck by lightning and set on fire. The flames soon spread, and within two hours the upper floor of the north-east wing was burnt out and the lower floors greatly damaged. The south-east wing was also seriously damaged. Several fire brigades turned out and prevented the total destruction of the mansion.——A telegram from Nashville, Tennessee, states that during a severe thunderstorm on Monday night, the circular building containing the cyclorama of the battle of Mission Ridge, was struck by lightning and completely ruined. The damage is estimated at $20,000.—— At about seven o'clock on Monday evening last a storm of considerable violence passed over Rotherham and district, and a farmer, of Thrybergh, near Rotherham, was struck by lightning and killed. He was engaged in haymaking, and was raking the hay up with a horse and rake when he was struck. During a thunderstorm which broke over Sprottau, in Silesia, the cavalry stables, where a number of soldiers were at work, was struck by lightning, and three men were killed.

Huddersfield.—On the 29th ult. the electric light station at Huddersfield was formally opened by the mayor. As a result of the inquiries of the municipal deputation, the high pressure alternating-current system was determined upon, and a contract was entered into with the Brush Company for the supply of plant and mains. The machinery already put in will provide for 9,000 8 c.p. lamps, but so great has been the demand for light that the plant is about to be doubled in capacity. The present plant comprises three Mordey alternators, having a total output of 250 kilowatts, driven from three compound vertical condensing steam engines, which are supplied with steam from four Babcock Wilcox boilers, having a total capacity of 800 H.P. The additional plant will comprise one 250-kilowatt alternator and steam engine of the same type as the others. Arrangements are made for running the alternators in parallel at 2,000 volts. The primary high-pressure mains are concentric, and have been manufactured by Messrs. Siemens Bros., and the low-pressure network is laid on the Callender-Webber system. There are four transformer sub-stations. The price charged for energy is 6d. per unit.

The Telephone Question at Glasgow.—From an able "official statement" in the *Glasgow Evening News*, it is evident that the National Telephone Company do not mean to allow the disadvantages of municipal telephony to be lost sight of. It cannot surely be contended, the Company argue, that a community of nearly 700,000 people should be taxed in order that a few thousand individuals, who are well able to pay a fair rate for their telephonic communication, should obtain the same at something less. No doubt municipal telephony would be a serious thing for the National Telephone Company, but it would not be ruinous. The fact that subscribers to a municipal exchange will not be able to communicate with other towns without paying an extra fee is also emphasised, though, of course, the same will probably be the case with subscribers to the National Telephone Company's exchange as soon as the trunk wires are transferred to the Post Office. There are two other points which it is thought have been lost sight of. The first is that the Postmaster-General will not give any license running beyond the time that is now fixed—namely, 18½ years, so that the whole capital expended by the Corporation would have to be redeemed in that time. The other point is this, that the Postmaster-General would never give a license to any person to establish a telephone exchange without paying the Post Office a royalty. Assuming that the municipal charge was £6 per annum, a 10 per cent. royalty on this would be 12s., which would be equal to a tax of 6s. per £1 (exclusive of income-tax) on the £2 profit which the Finance Committee show on paper per annum per subscriber, leaving them the sum of 28s. per subscriber to redeem the whole capital outlay.

Chicago Exhibition.—The following letter from Mr. Conrad Cooke appeared in *The Times* of Wednesday :—

SIR,—As one of the judges for the World's Fair, nominated by the Royal British Commission, and having just returned from Chicago, I think it may not be without interest to your readers if I give a view of the position of the technical judges from the judges' standpoint by relating my own experience. At the end of March last I was asked by one of the Royal Commissioners if I would be willing to go to Chicago to act there as judge in the section Electricity, and the sum of £200 was mentioned as probably the lowest amount that would be paid for expenses (the professional labour involved being gratuitous). To this I assented, and I was told that "the work of the judges shall commence not later than June 1, 1893." I accordingly made the necessary preparations and secured my passage so as to be in Chicago on that date. Some weeks later, however, I was officially informed that "the work of the judges will commence in the middle of June" and that "the sum of £150 will be assigned to each judge." On the day of my departure from London (obviously too late to make fresh arrangements), it was officially notified to me that "the work of the judges has been postponed from June 15th to July 1st." I arrived in Chicago on June 1st, resigned to an enforced delay of a month, but quite unprepared for a further postponement. In about three weeks, however, the authorities decided to postpone the work of the judges to the latter end of July or the beginning of August, so that it would be the end of September or the beginning of October before the work, under the most favourable conditions, could be finished. My professional engagements in Europe made it impossible for me to remain so long away, so I had no course left to me but to send my resignation to the Royal Commission. There were, however, other than personal reasons for resigning the position ; the conditions imposed upon the judges are, in my opinion, impossible to be fulfilled. According to the instructions, each judge is required to examine every individual object exhibited by every exhibitor in his section, and to make a report in writing, over his signature, thereon, stating his reasons for giving or withholding an award to that particular object ; and, moreover, he has, in addition, to prepare an abstract report upon each object he examines, and such abstracts are to be inscribed in the diploma to be presented to the exhibitor, while the full reports are to be published afterwards, and will form part of the literature of the exhibition. The fulfilment of such a condition would involve many months of the closest possible work. When it is considered that the duties of a judge necessitated an absence from England of some 18 weeks instead of 10 (as originally intimated), that one cannot live properly in Chicago for much less than £2 per diem, and that the prescribed conditions were, in my opinion, altogether impracticable, it will be seen that to resign the position was the only course open to me, although I understand it involves the loss of any allowance for expenses. I ask you to publish this letter, not with the view of ventilating any personal grievance, but with the object of placing on record the difficult position in which the judges at the World's Columbian Exposition have been placed by the want of proper consideration on the part of those in authority in the matter.

The Madras Electric Tramways.—The present position of the Madras Tramway question is a source of fruitful discussion in the columns of the local prints, says the *Indian Engineer*, and something like a deadlock seems to have been reached. The refusal of the Government of Madras to extend the time within which the Company is bound to find a certain amount of capital may just possibly bring matters to a conclusion—a conclusion which all who take interest in our material development must view with concern. Why shares taken by contractors in part payment should not be allowed for in a statement of share capital we cannot precisely see ; and we should like to know upon what logical grounds such a course is defended. That, however, is a question for lawyers to decide ; what more immediately concerns us is the possible wrecking of a scheme of engineering enterprise. For the Madras Electric Tramways Company (Limited) we have never had any great love, as former articles in these columns will have shown ; but it is greatly to be deplored that a quibble of the nature we have indicated should be allowed to prevent the supply of Madras with tramways. We are not informed that the position is without elements of hope, and we should be sorry to think that such was the case. Apart from the benefits that Madras may reasonably hope to gain from a system of tramways, the fact that electric traction was to be used for the first time in India in such a way lent additional interest to the operations of the Company. The project, too, of utilising town refuse for the generation of the necessary power is also something new to India, but in this particular we are inclined to think that the Company cut off a bigger chunk than it could well chew. The point of interest at the moment is, however, the action of the Madras Government ; if the enterprise is legitimate, then, in the name of all that is reasonable, let it have a fair show. If the present action is to be taken as meaning that after full investigation the Government is not convinced of the legitimacy of the undertaking, then we are sorry for the shareholders who have paid their four rupees per share. This we understand from the prospectus to be returnable in case of a partial allotment ; and after the expense the Company has already incurred, it will be interesting to see how repayment of application money is effected.

A GRAVITATIONAL AND ELECTROMAGNETIC ANALOGY.—II.

BY OLIVER HEAVISIDE.

In my first article on this subject (*The Electrician*, July 14, 1893, p. 281), I partly assumed a knowledge on the part of the reader of my theory of convective currents of electrification ("Electrical Papers," Vol. II., p. 495 and after), and only very briefly mentioned the modified law of the inverse squares which is involved, viz., with a lateral concentration of the lines of force. The remarks of the Editor* and of Prof. Lodge† on gravitational aberration, lead me to point out now some of the consequences of the modified law which arises when we assume that the ether is the working agent in gravitational effects, and that it propagates disturbances at speed v in the manner supposed in my former article. There is, so far as I can see at present, no aberrational effect, but only a slight alteration in the intensity of force in different directions round a moving body considered as an attractor.

Thus, take the case of a big Sun and small Earth, of masses S and E, at distance r apart. Let f be the unmodified force of S on E,

thus
$$f=\frac{\mathrm{SE}}{4\pi r^2 c}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

using rational units in order to harmonise with the electromagnetic laws when rationally expressed. Also, let F be the modified force when the Sun is in motion at speed u through the ether. Then‡

$$\mathrm{F}=f\times\frac{1-s}{(1-s\sin^2\theta)^{\frac{5}{2}}}, \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where s is the small quantity u^2/v^2, and θ is the angle between r and the line of motion. ("Electrical Papers," Vol. II., pp. 495, 499).

Therefore, if the Sun is at rest, there is no disturbance of the Newtonian law, because its "field of force" is stationary. But if it has a motion through space, there is a slight weakening of the force in the line of motion, and a slight strengthening equatorially. The direction is still radial.

To show the size of the effect, let

$$\left.\begin{aligned} u&=3\times10^7 \text{ centim. per sec.}\\ v&=3\times10^{10} \text{ ,, ,, ,,}\end{aligned}\right\} \quad . \quad . \quad . \quad (3).$$

This value of u is not very different from the speed attributed to fast stars, and the value of v isthe speed of light itself.

So we have
$$s=\frac{u^2}{v^2}=\frac{1}{10^6}, \quad . \quad . \quad . \quad . \quad . \quad (4)$$

i.e., one millionth. All perturbing forces of the first order are, therefore, of the order of magnitude of only one-millionth of the full force, even when the speed of propagation is as small as that of light.

The simplest case is when the common motion of the Sun and Earth is perpendicular to the plane of the orbit. Then $\theta=\frac{1}{2}\pi$ all round the orbit, and

$$\mathrm{F}=f(1+\tfrac{1}{2}s), \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

showing an increase in the force of attraction of S on E of one two-millionth part, without alteration of direction or variation in the orbit.§

But when the common motion of the Sun and Earth is in their plane, θ varies from 0 to 2π in a revolution, so that the attraction on E, whilst towards the Sun's centre, always undergoes a periodic variation from

$$\mathrm{F}=f(1-s) \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

when $\theta=0$, to
$$\mathrm{F}=f(1+\tfrac{1}{2}s), \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

when $\theta=\frac{1}{2}\pi$. The extreme variation is, therefore, $\frac{3}{2}sf$, according to the data used. The result is a slight change in the shape of the orbit.

* *The Electrician*, July 14, p. 277, and July 28, p. 340.

† *The Electrician*, July 28, p. 347.

‡ This is the case of steady motion. There is no simple formulæ when the motion is unsteady.

§ But Prof. Lodge tells me that our own particular Sun is considered to move only 10·9 miles per second. This is stupendously slow. The size of S is reduced to about 1/360 part of that in the text, and the same applies to the corrections depending upon it.

But, to be consistent, having made v finite by certain suppositions, we should carry out the consequences more fully, and allow not merely for the change in the Newtonian law, as above, but for the force brought in by the finiteness of v which is analogous to the "electromagnetic force." This is very small truly, but so is the above change in the Newtonian law, and since they are of the same order of magnitude, we should also count the auxiliary force. Call it G. Then

$$\mathrm{G}=\mathrm{F}\times\frac{xqu}{v^2}\times \mathrm{V}\mathbf{q}_1\mathrm{V}\mathbf{r}_1\mathbf{u}_1, \quad . \quad . \quad . \quad . \quad (8)$$

where F is as before, in (2) above, q is the actual speed of the Earth (not the same as u), and in the third vectorial factor, $\mathbf{q}_1$, $\mathbf{u}_1$, and $\mathbf{r}_1$ are unit vectors drawn parallel to the direction of the Earth's motion, of the Sun's motion, and from the Sun to the Earth. We see at once that the order of magnitude cannot be greater than that of the departure of F from f, before considered, because u and q will be of the same order, at least when u is big. As for x, it is simply a numerical factor, which cannot exceed 1, and is probably $\frac{2}{3}$.

The simplest case is when the motion of the Sun is perpendicular to the orbit of the Earth. Then

$$\mathrm{G}=\mathrm{F}\times xs \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

gives the tensor or size of the auxiliary force. It is radial, but outwards, so that the result is merely to reduce the size of the previous correction, viz., the difference of F from f in the same motional circumstances.

But when the line of motion of Sun is in the plane of the orbit, the case is much more complicated. The force G is neither constant (for the same distance) nor radial, except in four positions, viz., two in the line of motion of the Sun, when the auxiliary force vanishes, and two when $\theta=\pm\frac{1}{2}\pi$, when it is greatest. But this force is still in the plane of the orbit, which is an important thing, and is, moreover, periodic, so that the tangential component is as much one way as the other in a period.

All we need expect, then, so far as I can see from the above considerations, are small perturbations due to the variation of the force of gravity in different directions, and to the auxiliary force. Of course, there will be numerous minor perturbations.

If variations of the force of the size considered above are too small to lead to observable perturbations of motion, then the striking conclusion is that the speed of gravity may even be the same as that of light. If they are observable, then, if existent, they should turn up, but if non-existent then the speed of gravity should be greater. Furthermore, it is to be observed that there may be other ways of expressing the propagation of gravity.

But I am mindful of the good old adage about the shoemaker and his last, and am, therefore, reluctant to make any more remarks about perturbations. The question of the ether in its gravitational aspect must be faced, however, and solved sooner or later, if it be possible. Perhaps, therefore, my suggestions may not be wholly useless.

CONDENSERS AND IDLE CURRENTS OF TRANSFORMERS.

BY PROF. PERRY, F.R.S., AND MILES WALKER.

Everybody knows that a condenser shunting the primary coil of a transformer causes a diminution in the effective current to be supplied when the secondary circuit is broken, that is, when there is no load upon the transformer. Although the mathematicians know all about this matter, there is some ignorance among ordinary students, and I think that the following numbers, calculated by Mr. Walker, will be found interesting.

The current to an unloaded transformer consists of the fundamental term of the same frequency as the primary voltage and there are other terms of three and five times the frequency. With these "other terms" the condenser has nothing to do; it cannot disguise them in any way; the total current always contains them. I shall not speak of them, as they may be imagined added on, and this saves trouble, for if the funda-

Digitized by Google

mental term only is considered we may imagine the permeability constant; that is, that the primary circuit of an unloaded transformer has simply a constant self-induction.

If at any instant V is the primary voltage, R and L the resistance and self-induction in ohms and secohms, and if K is the capacity of the condenser in farads, the current in the coil is $\frac{V}{R+L\theta}$, and the current into the condenser is $K\theta V$, where θ stands for d/dt; so that the sum is $K\theta V + V/(R+L\theta)$. If $V = V_0 \sin pt$, the amplitude of the total current is

$$V_0\sqrt{\frac{(1-KLp^2)^2+K^2R^2p^2}{R^2+L^2p^2}},$$

and the *lag* of this total current behind the voltage is

$$\tan^{-1}\frac{Lp}{R} - \tan^{-1}\frac{KRp}{1-KLp^2}$$

To study this Mr. Walker has taken numbers from a Hedgehog transformer.

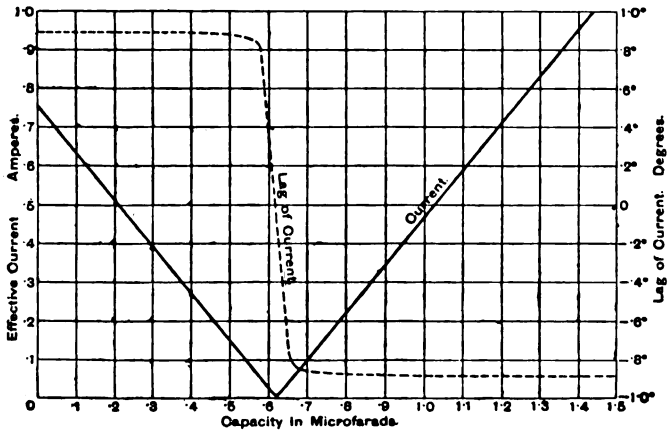
$$R = 24 \text{ ohms}, \quad L = 6{\cdot}23 \text{ secohms}, \quad p = 509,$$

or a frequency of about 81·1 per second.

The effective voltage (or $V_0 \div \sqrt{2}$) is 2,400 volts.

Then for certain values of K Mr. Walker has calculated values for the effective current in amperes and the lag in degrees.

These results have been plotted by Mr. Walker on squared paper. The current curve (*see* Figure), is a hyperbola which is



undistinguishable except just at the vertex, from two straight lines. The total current is a minimum when $K = L/(R^2+L^2p^2)$, in this case 0·618 microfarad; and the effect of the condenser has been to diminish the total current in the ratio of the resistance to the impedance. It is interesting on the curve to note how the great lag changes very suddenly into a great lead.

NOTES ON THE ELECTRIC ARC WITH SOME EXPERIMENTS ON THE ARC UNDER PRESSURE.

BY DR. LOUIS DUNCAN, A. J. ROWLAND, AND R. J. TODD.

Twenty-five years ago Edlund, to account for some of the phenomena which accompany the production of the electric arc, supposed that there existed in it a constant counter electromotive force, the flow of the current being opposed by this and by the ohmic resistance of the column of heated air and carbon vapour forming the arc. His formula was, $E = a + b\,c\,l$, where E is the potential difference at the terminals, a the counter E.M.F., b a constant, c the current, and l the length of the arc.

That this formula is not correct may be seen by an inspection of Table I, where the results are approximately represented by

$$E = a + \frac{b\,l}{c\cdot 7}.$$

Other formulæ have been used or suggested; for example, S. P. Thompson suggests $E = a + \frac{b\,l}{c}$, and Cross and Shepard employed $E = a\,c + b\,c\,l$.

In each case the formula fits pretty closely the experiments on which it is based, but does not agree with experiments made under different conditions. In fact, almost any results may be obtained by modifying the size and composition of the carbons, and it is of the greatest importance to find what part of the phenomenon is constant and what is variable. The existence of the counter E.M.F. in the arc—supposing it does exist—has been accounted for in two ways: by the vaporisation of the positive carbon, or by the thermo-electric effect of the carbon-carbon vapour couple which exists while the arc is burning. It seems to us that both of them must play a part in the phenomenon. As far as the vaporisation of the carbon is concerned, this represents a certain amount of energy taken from the current; therefore there must correspond to it a fall of potential a such that $a\,c$ represents the energy necessary to vaporise the carbon. The amount of carbon vaporised may be calculated from the electro-chemical equivalent of carbon, while the value of a could be calculated if we knew the energy required to vaporise one gramme of carbon. Any attempt to discover a counter E.M.F. due to this cause by looking for a reverse effect on suddenly stopping the direct current must fail, as the E.M.F. stops simultaneously with the direct current. Such an E.M.F., if it exists, must remain constant as long as the temperature of volatilisation of the carbon remains constant. If the temperature is raised—by pressure, for instance—this E.M.F. should increase. As far as the thermo-electric effect is concerned, there is no reasonable doubt of its existence, since we have a composite circuit with two junctions at widely-different temperatures. The temperature of the positive carbon is—under fixed conditions of pressure and composition of carbons—independent of the distance apart of the carbons and of the current, but the temperature of the negative carbon depends on both of these. It should be possible to detect this E.M.F. by shutting off the current and looking for a reverse effect. If we accept the vaporisation theory entirely, the counter E.M.F. would be independent of the length of arc and current; if we accept the thermo-electric theory we would look for a much more considerable lowering of the voltage in an alternating as compared with a continuous arc, than really exists. Neither supposition will, by itself, explain the phenomena.

The total potential difference, then, should, for given conditions, be represented by $E = a + f(l)\,f(c) + b\,f''(l)\,f'(c) +$. Before giving the results of our experiments on the arc under pressure, we wish to call attention to one of the most remarkable of the phenomena exhibited by the arc—a phenomenon which has been often observed, but for which we have seen no rational explanation.

By changing the current of the arc, using cored carbons $\frac{3}{8}$in. in diameter, we obtained the following results:—

Table I.—*Atmosphere pressure.*

Volts.	Amperes.	Apparent resistance.	Length in inches.
65·0	3·1	21·0	$\frac{1}{8}$
58·5	4·6	12·7	,,
55·0	6·14	8·96	,,
54·8	6·15	8·91	,,
52·5	7·7	6·82	,,
52·0	8·0	6·5	,,
49·2	9·82	5·01	,,
47·5	11·26	4·21	,,
46·5	12·75	3·65	,,

The only explanation admissible is this: the effective E.M.F. is equal to E, the applied E.M.F., minus the constant counter E.M.F. a due to the volatilisation of the carbons, minus the variable counter E.M.F. a' due to thermo-electric effects. The arc resistance would vary inversely as the current, provided, as might easily be the case, the section of the arc varied directly as the current.

We have, then, $c = \frac{(E-a)-a'}{\frac{b\,l}{c}}$,

a' being a function of c. If now we increase c we decrease a' and also $\frac{b\,l}{c}$, and E will decrease until the equation holds

Digitized by Google

again. For instance, suppose

$$a = 30 \qquad a' = 15 \qquad c = 10 \qquad b\,l = 5,$$

then $$10 = \frac{E - 30 - 15}{\frac{5}{10}}, \text{ and } E = 15.$$

Now, suppose we increase c to 20 and a' changes to 10,

then $$20 = \frac{E - 30 - 10}{\frac{5}{20}}, \text{ and } E = 45.$$

It is evident that whether E increases or decreases depends, first, upon the decrease of a' with the increase of current, and, second, upon the variation of the arc resistance with the current. Both of these will depend on the size and composition of the carbons and their distance apart. So it is very easy to see why different observers have obtained different results and deduced entirely different formulæ.

With solid Carré carbons ¼in. diameter the results were different, the potential difference remaining, approximately, constant under wide variations of current.

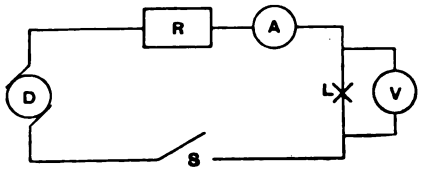


FIG. 1.

Arc under Pressure.—The apparatus used consisted of an iron cylinder, having stuffing boxes in the ends, through which the rods holding the carbons passed. The upper rod had a rack and pinion for adjusting the arc, and a scale for measuring its length. There was a pressure gauge on top. An air pump,

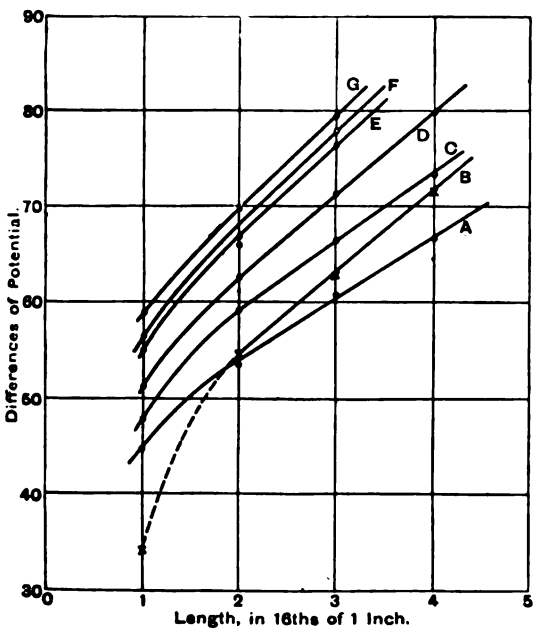

FIG. 2.—A, one atmosphere; B, vacuum; C, two atmospheres; D, four atmospheres; E, six atmospheres; F, eight atmospheres; G, ten atmospheres.

connected with the cylinder, was run by an engine. There were two glass windows in the cylinder at right angles to one another, so the carbon could be observed. A water jacket around the cylinder kept it cool. A shunt dynamo which we had somewhat overcompounded supplied the current, which, in most of the experiments, was kept constant at 6 amperes. The arrangement is shown in Fig. 1.

In determining zero readings on the scale, a high resistance, made of graphite, was thrown in series with R. This was so proportioned that when the carbons were apart the reading on the voltmeter was about one-third that of the dynamo. When the carbons touched, the voltmeter fell to zero. Each reading was repeated a number of times. No readings could be obtained while the air in the cylinder was being disturbed.

The results are given by the curves and tables. As c remained constant during the experiments, the value of a, considered as a constant, may be calculated from $E = a + b\,l\,f'(c)$. No matter what the function f' may be. Doing this we find the values of a given in Tables III. and IV. Leaving out values

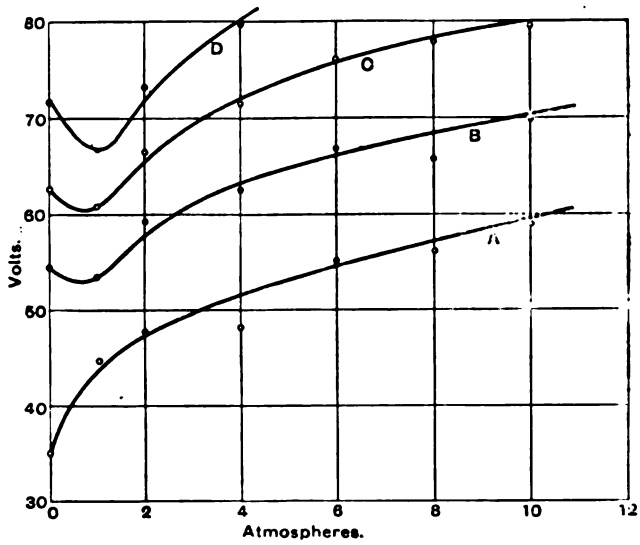

FIG. 3.—A, $\frac{1}{16}$in. length; B, ⅛in. length; C, $\frac{3}{16}$in. length; D, ¼in. length.

for the vacuum, which are low because of the very low reading taken for $\frac{1}{16}$in., we see that by combining the values for $\frac{1}{16}$in. with the ⅛in., $\frac{3}{16}$in., and ¼in. we get increasing values of a as the length increases, while if we take $\frac{1}{16}$in. and ⅛in., then ⅛in. and $\frac{3}{16}$in. and $\frac{3}{16}$in. and ¼in., the increase is more rapid.

Table II.—*Table of Average Volts, Constant Current 6 amperes.*

10	48·1	50·7	.....

The tables show that a varies with l for all the pressure employed, for no function of l substituted for l in the formula will make

Digitized by Google

a constant in the two tables. The absolute values of a, given in the tables, are probably not very accurate, as a small error in the voltages is considerably exaggerated in the results, especially in Table IV. So, in Table I., it is impossible to get any formula to fit the results. If we try to use $E = a + b\,l\,f(c)$, a seems to decrease as c increases, and the formula $E = a + \frac{bl}{c \cdot 7}$ is only approximately correct. The increase of E with the increased pressure is shown in Figs. 2 and 3.

The behaviour of the arc in partial vacuum is curious. The constant counter E.M.F. is probably lower, and the positive carbon is not so hot, but the negative carbon seems to cool proportionately faster than the positive, so the variable E.M.F. increases.

Looking at Tables II. and III. we see that the fall of potential due to ohmic resistance does not seem to increase in any regular way with the pressure.

Table V.

Length of arc. inches.	Atmospheres.	
	1	4
$\frac{1}{16}$	43·08	48·87
$\frac{1}{8}$	51·22	58·3
$\frac{3}{16}$	57·95	67·5
$\frac{1}{4}$	65·64	...

Table VI.

Atmospheres.	Values of a'.					
	$\frac{1}{16}$" & $\frac{1}{8}$" lengths.	$\frac{1}{16}$" & $\frac{3}{16}$" lengths.	$\frac{1}{16}$" & $\frac{1}{4}$" lengths.	$\frac{1}{16}$" & $\frac{1}{8}$" lengths.	$\frac{1}{8}$" & $\frac{3}{16}$" lengths.	$\frac{3}{16}$" & $\frac{1}{4}$" lengths.
1	34·94	35·64	35·56	34·94	37·76	34·88
4	39·44	39·55	...	39·44	39·9	...

The very small values of a, however, shown in Table III., are due to the low reading at $\frac{1}{16}$", where there was, in all probability, a hissing arc. If we take the values from readings at $\frac{1}{8}$ and $\frac{3}{16}$ and $\frac{1}{4}$, we find them closer to the values for the other pressures.

To determine the effect of the surrounding gas some experiments were tried in an atmosphere of carbon dioxide. The results are shown in Tables V. and VI. Although the values are a trifle lower than for air, they in general confirm the experiments of S. P. Thompson, who found that the arc was independent of the nature of the surrounding gas.

We conclude, then :—

1. That the counter E.M.F. of the arc is made up of two parts, an E.M.F. due to the volatilisation of the carbon, independent of the length of the arc, of the current, and of the size of the carbons, but dependent on the pressure; and a variable thermo-electric E.M.F. depending on the length of the arc, the current, the size of the carbons, and the pressure.

2. As the tendency of the arc is to increase in cross-section with the current, its resistance will decrease with the current.

3. The apparently anomalous decrease in E.M.F. with increase of current is probably due to the decrease of the thermo-electric counter E.M.F. caused by the heating of the negative carbon, together with the decrease of ohmic resistance referred to above.

4. There is a constant increase of potential difference with pressure above atmosphere for a given current and length of arc. Below one atmosphere the potential difference again increases.

5. The counter E.M.F. apparently increases with pressures above one atmosphere, while the ohmic resistance does not greatly change.

The Glasgow-Belfast Telephone Trunk Line.—The Post Office notify that the charge for telephonic conversations between Belfast and Glasgow is reduced from 5s. to 3s. for three minutes.

POSSIBLE AND IMPOSSIBLE ECONOMIES IN THE UTILISATION OF ENERGY.*

BY PROF. ALEX. B. W. KENNEDY.

I myself regret very much, and I fear you will regret even more, that my subject to night is one which does not lend itself to illustration by example, or by experiment, and only to a small extent to illustration by diagram. It is essentially a matter of figures and of percentages, a matter involving the discussion of mechanical balance-sheets, and the estimation of prime costs in the department of Applied Physics. I feel sure that it is an important matter; I wish I could feel equally sure that I had the power to make it an interesting one.

The importance of the subject is not difficult to understand if you realise the enormous results—so large as to be even of national interest—which depend upon what can, and what cannot be done in the way of utilising energy. Economy in energy may mean wealth and prosperity to a nation; waste in energy may mean diminished commerce and general depression. We have always many advisers and counsellors with us; it is very far from easy to know, among the multitude of voices, who has wisdom, and who has only words. I wish to try to-night to give you some criteria by which to judge for yourself.

As an engineer, I am bound to take my stand at once on the firm basis that nothing is impossible except perpetual motion and the transmutation of metals. I suppose it would hardly be safe, indeed, to be too sure about the last, for one cannot help having an uneasy suspicion that Prof. Dewar will tell us shortly that down about 273 degrees everything is the same thing, or else is everything else, and that the difference between gold and lead, after all, is nothing more than a matter of thermo-dynamic function.

But at perpetual motion one can clearly make a safe stand, no matter how cold or how hot the physicists may make things for us. And in essence all the things which I shall have to characterise as *impossible* are really perpetual motions, or what is the same thing, attempts to get more out of something than there is in it; to get 21s. out of a sovereign without having any benevolent and foolish person standing by to provide the extra shilling.

It is familiar to even the least mechanical in this room that there are, in Nature, vast—I dare not say inexhaustible—sources from which we can obtain energy by certain more or less familiar processes. I say "obtain" energy, using the most familiar expression, but perhaps the word is not a very happy one. We require energy to light lamps, to smelt metals, to drive factories, to pull trains, but in no case do we obtain it ready made as we draw water from a well. There is plenty of it in existence, plenty to be had, but to get it in the form in which we want it we have always to transform it from some other form to the required one.

Notwithstanding the suggestion that has been made, that steam engines are unnecessary in the central station because the dynamos might so easily be driven by electricity, there is in every electric lighting station in this city, for instance, first a transformer of the natural energy of chemical combination into heat, then the transformation of heat energy into mechanical energy in a steam engine, then the transformation of the mechanical energy into electrical energy in the dynamos, and lastly the transformation of electrical energy into light, and also very largely back again into heat, in the lamp.

Often the transformations are not so numerous as in this case, but they always exist to some extent, and all the possibilities and impossibilities are practically related to some or other of these transformations. And with them are those fundamental facts which I will ask you to note.

1. Every transformation of energy is accompanied by some waste of energy.

2. Every transformation occurs in absolute accordance with certain phenomena which reproduce themselves so exactly that they have come to be called *physical laws.*

3. All the quantities which can appear in every transformation are as exactly measurable and have been as exactly measured as could be the temperature of this room, or the

* Lecture given at the Royal Institution, April 21, 1893.

Digitized by Google

breadth of Albemarle-street. There is no room in these cases for guessing, or for dealing in mere wordy generalities, or speculations. A man who says that he is going to produce 25s. out of a sovereign would be laughed at. But he is no more talking nonsense than the man who proposes, for instance, to double the present efficiency of a pound of coal.

As to the first point, I use the expression waste rather than loss because the energy cannot well be said to be lost. A thing is, perhaps, incorrectly described as lost when one knows where it is, but if it has passed away uselessly it may at any rate be said to be wasted so far as the direct object of the transformation is concerned. The amount of energy lost in a transformation is measured by noting what is called the efficiency of the transformation, which is usuallly expressed as a percentage. A transformation with only one per cent. loss, for example, would be said to have an efficiency of 99 per cent., and so on. Perpetual motions are simply transformations of 100 per cent. efficiency; indeed, nowadays, one finds folk occasionally who are content with nothing less than 200 per cent. on paper.

In dealing with my second and third points, I am aware that I am trenching on much more difficult and delicate ground. "Known physical laws" (?) one may be, and for that matter one is, very frequently met with the objection that the phrase is unjustifiable, or, at any rate, inapplicable in these cases. All the laws, we are told, are not known; all the phenomena even are not known; discoveries may be made which will turn everything topsy-turvy at one stroke; and why, therefore, attempt, at the outset, to put foolish limitations to progress by saying that anything is impossible, merely because of such obstructives as physical laws. It is, alas, too true, that few things are completely known, at least I fully confess it for myself, and I believe there are those here whose knowledge of physical laws is incomparably greater than mine who would quite as freely admit the limitations of their knowledge.

But it is noticeable that this particular objection to saying that anything is impossible on account of our ignorance of what is possible, is, oddly enough, seldom thrown out by those who know most, even although, among other things, they well know their own ignorance. It seems always to be urged most strongly by those who know least. To the latter—to the good folk who dabble in physics and chemistry, and patents and syndicates—it is always possible to conceive that some new law or force, or source of energy, or what not, will rise, Minerva like, fully equipped for use in the universe, and particularly equipped for making their individual fortunes out of a casual suggestion or a random experiment. With them, also, it is always a first impulse to treat each new phenomenon as an exception, and to invent a new law on purpose for it, rather than to try if it can be explained in some hum-drum fashion by an old one.

I think it is not impossible to arrive at some understanding as to how far existing knowledge can be held to be final, and how far or in what directions it is provisional. I mean, of course, so far as affects our particular object of saying what is, and what is not, possible in one special direction.

It seems, perhaps, contradictory, but I think it is true, that our superstructure in physical knowledge is much more solid than our foundations. The position is indefensible structurally and ethically, but it actually appears to represent the facts. Our knowledge of the ultimate constitution of matter, and particularly of the ultimate constitution of "not-matter," cannot be said to be accurate as yet. Is this table a mass of atoms, turning on their own axes, and twisting round one another and themselves in inconceivable complexity of motion? Or is the most charming lady in this room a congeries of whirling vortex rings interlaced in tangles which no poet has yet attempted to unravel or describe? Are we pervaded by an ether, or do we pervade an ether, or are we, or is it under a pressure of millions of tons on the square inch? These are, no doubt, fundamental questions, and yet I doubt if even the most distinguished physicist living would venture to be very positive in his answers to them.

But higher up in the scale matters are different, and it is as well that we should remember that there are physical chemical facts and numbers that are just as fully established, although they refer to phenomena which we cannot entirely follow, as are the figures of the nautical almanack.

Let me take the combustion of coal as an example, with the external phenomena of which we are all familiar. Chemists have analysed the coal and know of what it consists; so much carbon, so much hydrogen, so much oxygen, and have measured for us that its elements in the combustion enter into various combinations, so that they can tell us exactly the maximum amount of heat energy which can be given out by the burning of a given weight of coal. Even apart from the extreme niceties of delicate laboratory work, we can probably say, without difficulty, within one or two per cent., the actual amount of heat energy in foot pounds which could be generated by the perfect combustion of any given 100 tons of coal lying in a yard. It may sound as if no one could, or would, deny this proposition. Yet I have often enough met people who were quite convinced that they possessed the secret by which an amount of heat equal to double this quantity could somehow be obtained. Our knowledge in this respect is quite independent of our ignorance of the ultimate nature of the coal

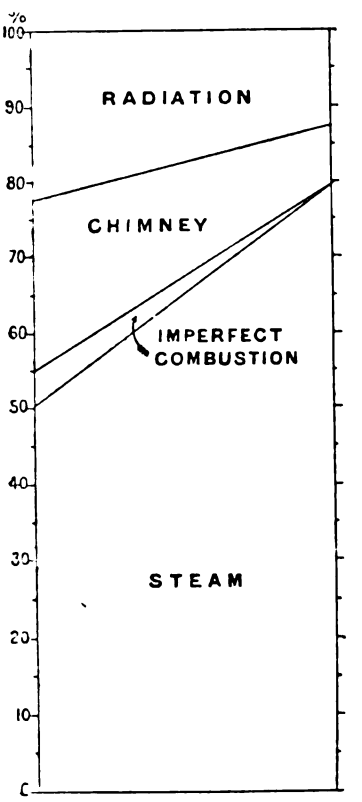

FIG. 1.

or the combustion. Assume, if you like, that hydrogen, like Homer, is not really hydrogen, but quite another element of the same name; assume carbon to be an allotropic form of oxygen; assume, if you please, that atoms are creatures of two dimensions, in series, connected by a little wire; but none of these assumptions, although they would be fundamental enough, will in any way invalidate our conclusions, or will enable us to get a single foot pound more of energy out of a ton of coal than we already know we can obtain. The facts we have to deal with are known, and independently of these fundamental general theories.

I have taken the phenomena of combustion as among those with which everyone is fairly familiar. Let us deal with it for a few minutes further in special illustration of my subject. Fig. 1 shows fairly accurately how far we have got in working at the efficiency of this kind of transformation. We start with a given amount of potential energy, known within very narrow limits, represented for us by a pound of coal with a sufficient weight of circumambient atmosphere. Let us represent this known amount of energy, as in the Figure, by 100 per cent. What becomes of all this if the coal be burnt in the furnace, say, of an

Digitized by Google

ordinary boiler, and if we endeavour to utilise this combustion energy in the conversion of water into steam? On the left hand of my diagram you may see what often enough happens in every-day careless working; on the right hand you may see what happens in thoroughly good working with real care, but without any special apparatus. You will see that the amount of heat taken up by the steam varies from 50 to 80 per cent. of the whole heat; that a small amount, from 5 per cent. down to nothing, is lost in imperfect combustion, that is the formation of carbonic oxide; that a very much larger amount goes up the chimney, having been expended in heating the waste gases; and that finally another large amount is purely wasted, being lost in radiation, and otherwise. Now I ask you to notice particularly two things, first, looking at the right hand of the diagram, how much there is still possible. The efficiency of the process is about 80 per cent. The remaining 20 per cent. is all that can be saved. Of this some portion must go in heating the chimney gases. It is the price paid for the draught of the chimney. We must also lose something by radiation; this is inevitable. We cannot look, therefore, to any very astounding increase of economy in boiler work over the best that has been done. Secondly, I ask you to notice what an enormous amount is possible on the left-hand side of the diagram which is impossible on the right—impossible, that is, because it has already been attained. Half of our possibilities—indeed, far more than half our possibilities of improving up to the best—it is infinitely harder to improve up from the best.

When anyone tells us that he has invented something, or some method, by which one ton of coal goes as far as two, we may know for certain one of two things: either he has made a mistake (which is possible enough) or else his standard of comparison has been unfortunately chosen. No doubt any saving is possible, if only one starts with a bad enough example. But then that saving has already been made in fact, and it is misleading, to say the least of it, to claim it as novel, or as depending on any new discovery. Surely all discoverers must start from the very forefront of their predecessors' position. What magnificent musicians, or artists, or climbers, or engineers we might prove ourselves to be if only we might choose our standard far enough down, and ignore all the art or science of the last 500 years.

This sounds absurd enough, when put in this fashion, but hundreds of thousands of pounds have been thrown away on elaborate schemes which, at best, could no more than bring bad and careless practice up to a level passed every day in places where care and common sense has been expended on the same matter. Plenty of room exists for raising the general average efficiency of boiler work; for, if the average working all over the country were brought up to the standard of the best, there would, probably, be one-third less coal used every year than is now actually burnt. The possible economy is truly not unimportant, but I fear it can only be brought about by methods too common-place to please humanity, who are just as ready to call for signs and miracles as they were 2,000 years ago.

The process which we have discussed is, perhaps, really rather to be called a transference than a transformation; at any rate, it falls into the category of transformation whose theoretical maximum efficiency is 100 per cent., or, allowing for absolutely inevitable losses, perhaps 90 per cent. But with many processes with which we have to do, unfortunately, our maximum theoretical efficiency is only 25 per cent., and instead of attaining 80 per cent. even of this we are often happy enough with half as much.

In this class of processes lie great possibilities, so that it is no wonder they are attacked from all sides, but—alas!—there lie here, also, equally great impossibilities, and the way to success is strewn with the bones of failures.

It will be worth while spending a few minutes in clearing up the fundamental notions about this matter. Suppose we have two samples of ore, one of which contains 30 and one 20 per cent. of metal. It is clear, in the first place, that the most perfect process or apparatus can only get for us 30 or 20 per cent. respectively of the weight of our raw material.

In this sense the maximum theoretical efficiency of the reduction may be called 30 or 20 per cent., as the case may be. It is no use finding fault with the apparatus because it will not give us more metal; the fault is in nature, which refused a richer ore to begin with. The efficiency of the ore is low, so to speak, not the efficiency of the plant or of the process.

But in the reduction of ore, as in every other such process, perfection is unattainable, and no apparatus would obtain for us, on a commercial scale, quite 30, or quite 20 per cent. of the weight of the ore in metal. Here comes in the efficiency of production, as distinguished from the efficiency of the ore. Now it is clear that the efficiency of production has nothing in the nature of things to do with the richness of the ore. I may use Fig. 2 to illustrate this. It is divided, as before, into equal parts, representing percentages. The sloping line represents on the left the 20 per cent. of metal, and on the right the 30 per cent. Suppose it happened that the metal in the richer ore were combined in such a way as to be much more difficult to reduce than that in the purer ore, we might, after all, be able to get only 15 per cent. of metal out of each, as is indicated by the horizontal line. In this case the efficiency of reduction would be 50 per cent. in the rich and 75 per cent. in the poor ore. Or, going further, it might quite well happen that we

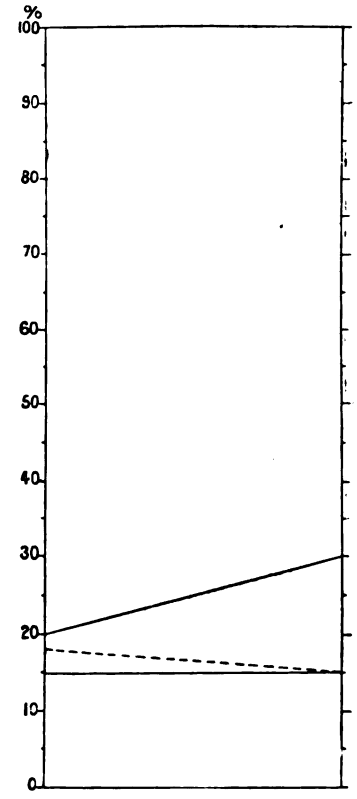

Fig. 2.

could get, say, 90 per cent. of the metal out of the poor, as against 50 per cent. out of the rich ore, as indicated by the dotted line in Fig. 2. In this case, the poorer ore would really pay us better than the other, for 90 per cent. of 20 per cent. is 18 per cent. of the whole weight, while 50 per cent. of 30 per cent. is only 15 per cent. of the whole weight.

I should like you clearly to bear in mind these double possibilities, for the secret of the whole matter is intimately connected with them. The efficiency of the ore—if one may so call the proportion of metal in it—has always a limiting value far less than unity, or 100 per cent. Only nuggets have an efficiency of 100 per cent., and these, I believe, only in novels. It is, moreover, fixed by nature, and not by us, so that we need not try to improve upon it except, of course, by looking out for the nuggets. The efficiency of the reducing process, on the other hand, is determined by us, and not by nature. Its theoretical maximum value is practically 100 per cent. How nearly this is reached in practical work is a matter of human skill in devising apparatus and carrying out processes.

I have used this quasi metallurgical illustration because, probably, it is more readily followed by those not familiar with

Digitized by Google

the subject than a physical illustration. But I must now ask you to come back with me to the region of physics, and try to apply the example to physical work.

In the very great majority of instances the mechanical energy which we utilise is originally obtained from the heat of combustion, transferred to some liquid or gaseous body, and by it made to cause certain parts in a machine to move, and to do mechanical work for us.

Now the actual cycle of physical process, isothermal, adiabatic, isodynamic or what not, which the steam or air or gas may go through is often a very complicated one, sometimes so complicated that it is a matter of considerable difficulty to say beforehand exactly what the maximum theoretical efficiency is—that is, in terms of our former illustration, to say exactly how much metal the ore contains. We always, however, know two things about it: first, that it is always far less than 100 per cent.; second, that it cannot exceed—and in all practical cases must fall considerably short of—a certain known limiting value much less than 100 per cent. This limiting value is the very familiar one which is written $\frac{T_1 - T_2}{T_1}$. I may venture to illustrate its meaning in a very familiar way by Fig. 3.

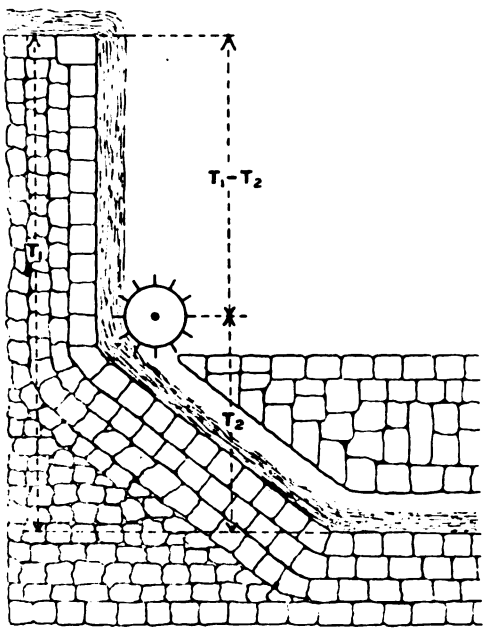

FIG. 3.

T_1 stands for the highest temperature measured above absolute zero, at which the working fluid receives heat. T_2 stands for the lowest temperature at which the fluid parts with its heat. The difference between the two temperatures, $T_1 - T_2$, is the working difference of temperature. In the Figure heights are substituted for temperatures, and $T_1 - T_2$ is the working head of water acting upon the imaginary water wheel. The value of the ratio which I have just given is always much less than unity, and must always be so, for the temperatures are measured from absolute zero, or, minus 273°C. The ratio is, in this way, always a proper fraction, which may be taken as representing what I have just been calling the richness, or the efficiency, of the ore. In the case of a modern steam engine its value is often about 30 per cent., in the case of a gas engine from 60 to 65 per cent.

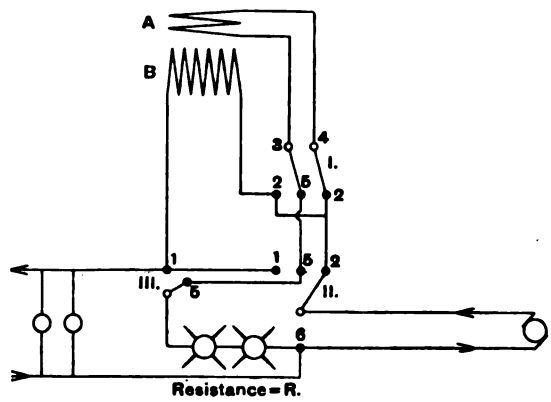
(To be continued.)

A COMMUTATOR ATTACHMENT FOR SIEMENS' DYNAMOMETER.*

The accompanying Figure shows a method, due to Behn-Eschenburg, of connecting a Siemens dynamometer to a circuit, whereby the current, the voltage, and the power may be successively measured. A and B are respectively the movable and fixed coils of the dynamometer, and I., II., and III. are switches or commutators for effecting the interchanges. To measure the current the switch I. is set as shown in the Figure, II. is set in contact with 5, and III. in contact with 5 also; this gives the value I for the current in the instrument. Then the switch III. is moved to 2, and the current I_1 is measured, the difference between the two currents being i. The power is, therefore, according to Fleming's method—

$$P = \frac{R}{2}(I_1^2 + I^2 - i^2),$$

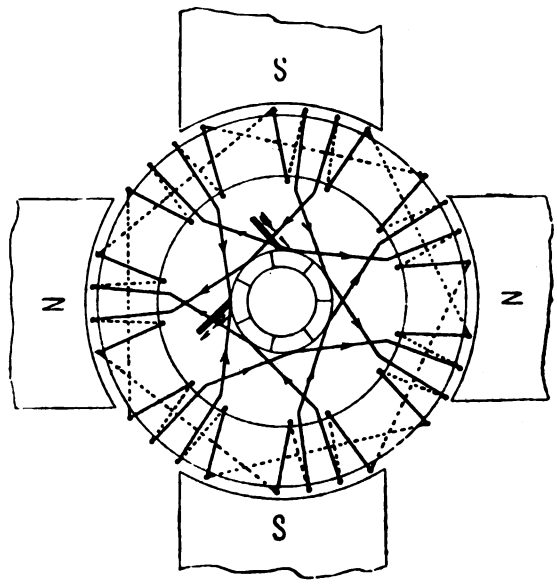
where R is the value of a non-inductive resistance, as shown. To transform the instrument into a voltmeter the switch II. is placed



in contact with 2, and III. in contact with 5. This measures the current i, which, multiplied by the resistance R, gives the voltage. The number of turns of wire on the movable coil is so small that for all values of the resistance R above 10 ohms the coefficient of self-induction of the coil is less than R/107. To measure the voltage the resistance R will, of course, be chosen, so that i is measurably within the range of the instrument.

A NEW ARMATURE-WINDING.

The accompanying figure shows a new kind of armature-winding, which has been designed by Mr. Ludwig Baumgart, and it is



intended chiefly for use with high-voltage four-pole machines. It is described in the *Elektrotechnische Zeitschrift* for June 9th, and is, as will be seen, a form intermediate between ring and drum forms, having twice as many wires outside as in; hence its value in high-pressure work. The author observes that for such uses machines may be conveniently made four-pole, and the addition of this armature, or one wound on a similar principle, enables full advantage to be taken of the increase in the number of poles in increasing the voltage. The armature has some of the advantages of the Gramme form, and is free from all patent rights.

SPECIALISING AND GENERALISING.

Among the eleven errors or "peccant humours" which are cited in the introduction to The Advancement of Learning, there is one which affirms "that after the distribution of particular arts and sciences men have abandoned universality, or *philosophia prima*, which cannot but cease and stop all progression. For no perfect discovery can be made upon a flat or level; neither is it possible to discover the more remote or deeper parts of any science if you stand but upon the level of the same science, and ascend not to a higher science." Regarding specialisation in science as a feature of the last fifteen or twenty years, it is strange to find that BACON saw, even in his time, before the foundations of modern science had been laid, a tendency to narrowness of work and thought. "For were it not better," he says, "for a man in a fair room to set up one great light, or branching candlestick of lights, than to go about with a small watch candle into every corner? . . . When you carry the light into one corner you darken the rest." Physical science being yet unfounded, it was his insight into human character rather than any inference from the absurdities of the schoolmen that led him to make this observation. There are many excuses for specialisation to-day. "The whole body of physick" is too wide for one man to master, and mere competition drives each man, by the principle of least resistance, to do either that which chance has thrown in his way, or that which by good luck he may be able to choose.

Specialists are the advance guard of the army of science, and after them come the rank and file with the "all-round men" in front. To specialists belong the exciting and difficult tasks of pioneering discovery, but an advance guard with no army behind it would be of little use. In its onward march

Digitized by Google

science soon comes up with the points already reconnoitred by the scouts, and their work is absorbed and systematised, and takes its place in the general body of knowledge. Unfortunately everybody wants to be a pioneer, and since modern science tends to sub-division into a host of minor inquiries, it is greatly to be desired that general surveys of its various branches should be taken now and then by liberal-minded men. The "*philosophia prima*" Bacon explains to be "primitive or summary philosophy, as the main and common way, before we come where the ways part and divide themselves."

There was some very profitable *philosophia prima* of this kind in the discourse delivered by Prof. Kennedy before the Royal Institution in April last, and in our present issue will be found the first portion of this discourse. He discusses many examples of efficiencies and explains in a singularly clear manner the difference between available and unattainable economies. The specialist busies himself with new valve motions, automatic governors and lubricating devices, and ultimately attains an economy which, measured by coal consumption, might have been secured at a hundredth part of the cost by more careful lagging of a steam pipe, draining of a feed pump, or common-sense use of a damper. Much of the discourse is occupied with possibilities and impossibilities of the use of the steam engine; and he points out the fields in which further economies may profitably be sought, and those in which ignorant inventors, incautious enthusiasts, unscrupulous prospectus writers, or science correspondents of daily newspapers may be left to disport themselves; since none can exclude them.

OBITUARY.

OLIVER SMITH.

We regret to record the death of Mr. Oliver Smith. The deceased was born at Great Yarmouth in 1833, and joined the Gutta Percha Company in 1851, in which year he took a part in the manufacture of the 1851 Channel cable from Dover to Calais. In 1854, he left the Gutta Percha Company to enter the service of Messrs. Glass, Elliot and Co. at Greenwich, and from 1861 to 1864 assisted in laying cables from Malta to Alexandria, from Ireland to Wales, and from Sardinia to Sicily. He was engaged on the first Atlantic cable of 1858 on the "Agamemnon," and when the "Great Eastern" was chartered to take out the new Atlantic cable in 1865 he was in charge of the electrical department on board at Sheerness, during the shipping of the cable. He also accompanied the expedition of that year, as also those of the Atlantic cables of 1866 and 1869 as electrical assistant to his brother, the late Mr. Willoughby Smith. From this time to the end of his life he was in the service of the Telegraph Construction and Maintenance Company, during the greater part of which time he was engaged as electrician at Endesby's Wharf, Greenwich, although occasionally assisting in cable expeditions.

He will be well remembered by those who were on board the "Great Eastern" by his plentiful fund of good humour and anecdote, which helped to a large degree, especially during the trying task of recovering the 1865 cable in 1866, to pass away many a dreary hour. His mesmeric entertainments during these expeditions were also much appreciated by those on board. His loss is greatly regretted by a wide circle of friends and acquaintances in all parts of the world. Of late years he had been in failing health; in fact, he was never the same after the death (about seven years ago) of his only son, also in the service of the Telegraph Construction Company, who died suddenly on his way home from the successful laying of a cable in the Far East, in which expedition he had charge of the electrical department.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 343.)

Edison for a long time made a socket joint, which was electro-plated with copper. The deposit of copper extending a short distance along both the wire and the filament. This made a good joint both electrically and mechanically, but it was abandoned some years ago in favour of a simpler form. The most common form of joint is a simple socket with a deposit of carbon at the junction in place of the copper deposit used by Edison. A simpler form is that made by a deposit of carbon without any tube or socket. The most simple form of all, however, is where the joint is formed by a small lump of carbon paste. This was used by Edison after the electro-plated joint had been given up. The deposited carbon joint is the most satisfactory as a joint, and is consequently the most widely adopted, though it is more troublesome and expensive to make than the paste joint. The deposited joint is made by heating the junction of the filament and wires by electric current in an atmosphere of hydro-carbon gas, or under a hydrocarbon liquid. The gas is seldom used, as it is too slow. The liquid gives a much more rapid deposit, but has the disadvantage of getting more or less all over the carbon and wires, and must consequently be driven off again before the filament is sealed into the bulb.

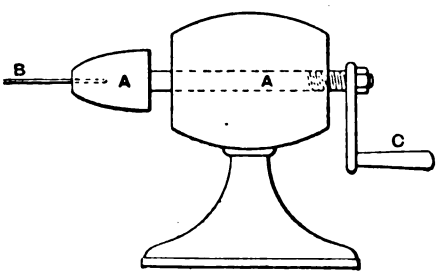

Fig. 9.

The first thing to be done towards making the joint is to prepare the platinum wires. The wire has first of all to be cut up into the lengths required. A deposited or paste joint can then be made without any further work on the platinum, but it is better to prepare the platinum in some way or cement will not have a good hold upon the wire. The plain wire is too smooth, and should be roughened or shaped so that the carbon cement has something to hold on by. The wire may be twisted into a spiral, forming thereby a socket into which the end of the filament is put. The spiral can be formed by twisting the wire with a machine like that in Fig. 9. A A is a spindle, with a needle B at one end and a handle C at the other. There is a screw thread on A which allows the needle to be rotated the same number of times, two or three usually, for each wire. The end of the platinum wire is inserted in a small hole close to the needle. The wire is held tightly, and the spindle rotated by the handle, thus twisting the wire two or three times round the needle. The wire is then slipped off the needle, straightened, and finished off with a small pair of pliers.

If a socket is required, it is better to make the tube form, which uses less platinum than the spiral. To make the tube, the wires are first flattened out for an eighth of an inch or so at the ends. This may be done by means of rollers, which may also be arranged to cut the wires at the same time. The wire being fed into the machine in a continuous length, is cut and flattened at one operation. The wires are then drawn through an ordinary wire draw-plate, which bends the flattened ends round into a tube. Before drawing through the plate, the flattened ends must be annealed by heating to redness in a Bunsen gas flame. If this is not done the

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of re-publication reserved.

Digitized by Google

flattened ends will be pulled off instead of being formed into a tube.

The filament is slipped into the socket, which is then squeezed upon it so as to hold it tightly. It is convenient to have the wires joined together by a bridge of glass before mounting in the socket, but it is not necessary.

If a butt or lap joint is to be made, the wires may be nicked near the end so as to form an indentation by which the deposit can hold on. An excellent way of making a butt joint is that which is used by the Edison-Swan Company. A small, flat head, like a pin-head, is formed on the end of the wires. The end of the filament is placed against the centre of this head, and carbon is deposited over the head and the end of the filament. As the carbon is deposited so as to completely cover up the head, it forms a very secure joint. Deposited carbon will always hold tightly to the filament. For filaments taking up to an ampere of current, platinum wire of 0·014in. diameter is generally used. The author has, however, known a lamp taking seven amperes to work perfectly well with this size of wire. For currents above one ampere larger wire should be used, and for more than five amperes several small wires are better than one large one.

The deposited carbon joint, as has already been mentioned, is made by heating parts of the wires and the filaments by a strong current of electricity in a hydrocarbon vapour, or

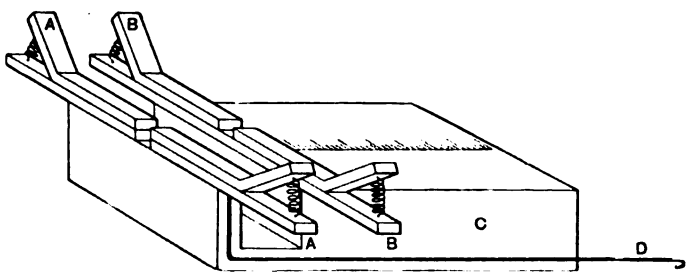

Fig. 10.

liquid. The hydrocarbon is decomposed by the heated wire and filament, and a deposit of carbon is the result. In order to make such a joint it is necessary to fix the wires and filament in a machine which will make the necessary electrical connections.

If a butt or a lap joint is to be made, the machine must be arranged so that the filament can be easily and quickly adjusted to its position opposite the platinum wires. For this purpose an instrument like that shown in Fig. 10 will answer the purpose.

There are two sets of spring contacts A A and B B, mounted on a wood block C, of which that part between the two sets of springs is cut away to the depth of about half an inch. The electrical connections are made to the spring contacts A A by means of the wire D and a corresponding wire on the other side of the instrument. The platinum wires are first clamped in A A, and the filament is then put into B B, so that its ends touch the ends of the platinum wires. The part which gets heated by the current is, of course, that between the two sets of clamps. The block is cut away to allow of a free circulation of the hydrocarbon.

When the deposit is obtained from a hydrocarbon vapour, the apparatus, with the filament and wires already placed in position, is hung on a support, which also conveys the current.

The liquid process is, however, more easily worked, and makes a more satisfactory joint. In this process the frame which holds the filament and platinum wires is hung on a support which also conveys the current, so that the part which is heated, and upon which the deposit is to be formed, is entirely below the surface of the liquid. Several filaments may be cemented at the same time, the frames being arranged in series, with a switch connected to each, so that any one of them may be cut out if necessary. It is more convenient to use a separate jar of liquid for each filament, though one large trough will answer the purpose. The jars are set in a metal or stoneware trough to catch any spillings of the liquid. It is also advisable that the whole of the bench at which the work is done be covered with zinc to prevent the wood from being soaked with the oil. An extinguisher to cover over the whole of the trough containing the pots of liquids may be provided in case of accident. There is, however, no danger from fire, unless very inflammable liquids are used. Any hydrocarbon liquid will produce a deposit on a carbon filament heated to redness below the surface of the liquid, though some liquids deposit very much more quickly than others. Vegetable oils, such as olive oil and linseed oil, produce a good deposit. They are, however, too viscous for use with very fine filaments, and the smoke which is produced has a bad smell. Turpentine deposits very rapidly, but the deposit is too soft. Benzoline or benzine rapidly deposit, but are too dangerous for ordinary use. Ether gives a rapid deposit, but, of course, cannot be used in the open. Mineral oils are generally used. The best kerosene oil gives a good and hard deposit, but is very slow. Crude petroleum, a black liquid containing mineral oils of various densities and flashing points, answers the purpose very well. A satisfactory liquid may be obtained by mixing one which deposits rapidly with one which does so slowly but gives a hard deposit; such a mixture, for instance, as four parts of best (high flashing point) kerosine to one part of turpentine. This mixture gives a sufficiently rapid and hard deposit, and is not dangerous to use. Even when the liquid has become very hot, a lighted match applied to the surface will be extinguished. While the deposit is going on a stream of dark smoke rises from the liquid. This smoke will burn as it bubbles up out of the liquid if it be lighted, but it can easily be blown out again. To obtain a proper deposit the joint is maintained at a bright red heat. There is no danger of firing the liquid so long as the joint is kept below the surface, and the current turned off before it is lifted out. The liquid may be fired by carelessness on the part of the operator. If, for instance, a joint breaks, as sometimes happens through excess of current when the depositing is going on, and so breaks the circuit, the operator may take out the filament and put in another, having forgotten to turn the switch off. As soon as the form with the new filament touches the contacts the joint will light up, and if it is not below the surface of the liquid, it will certainly set fire to the oil, if it be an inflammable one.

The strength of current used in making a joint is many times greater than the joint will ever be called upon to carry afterwards. In order to join a filament six mils in diameter to platinum wires of fourteen mils with tube sockets, the deposit to extend for a tenth of an inch along each leg of the filament, about twenty volts will be required to start the deposition, *i.e.*, to make the ends of the filament bright red-hot under the oil. As the deposition of carbon proceeds, the ends of the filament become rapidly duller. The thickness of the filament is increased, and, therefore, the cooling surface; while the resistance is at the same time diminished, and as there is a regulating resistance in the circuit, having a considerable resistance compared with that of the joint, the current rises only a very little. It is, therefore, necessary to cut out some of the regulating resistance and increase the current so as to keep the joint at a bright red heat. In this way the current will be gradually raised to at least twelve amperes before the joint is large enough, with a sufficient amount of deposit on the platinum. The volts will fall as the current is raised. With the best kerosene oil it will take ten minutes to make this joint. If the operation be hurried by turning up the current too fast, the joint will probably break, and both the filament and the wire will be spoiled by the arc which will be formed at the break. With one-fifth part of turpentine added to the kerosene, the time occupied can be safely reduced to one minute and yet produce a good hard joint.

The filaments may be flashed either before they are mounted or afterwards, or both before and after. Almost any hydrocarbon may be used, but for each one there will be certain conditions which will give the best results. Thus, one will work best if the filament be made very bright indeed, and another may only require a moderate temperature. One may require to be at a considerable pressure, while another must be much rarefied.

(To be continued.)

THE LUMINIFEROUS ETHER.*

I intend to bring before you to-night a subject which the study of light has caused me to think a good deal about; I refer to the nature and properties of the so-called luminiferous ether. This subject is, in one respect, specially fascinating, scientifically considered. It lies, we may say, in an especial manner on the borderland between what is known and what is unknown. In the study of it it is quite conceivable that great discoveries may be made, and, in fact, great discoveries have already been made, and I may say even quite recently, and we do not at present know how much additional light on the system of Nature may be in store for the men of science; possibly even in the near future, possibly not until many generations have passed away. I will assume, as what is familiarly known to you all, and what is well established by methods into which I will not enter, that the heavenly bodies are at an immense distance from our earth. More especially is this the case with the fixed stars. Their distance is so enormous that even when we take as a base line, so to speak, the diameter of the earth's orbit, which we know to be about 184 millions of miles, the apparent displacement of the stars due to parallax is so minute as almost to elude our investigation. Nevertheless that distance is more or less accurately determined in the case of a few of the fixed stars. But the vast majority, as we have every reason to believe, are at such an enormous distance that even this method fails with them.

To give a conception of the immense distance of the fixed stars, I will assume as known that light travels at the rate of about 186,000 miles in one second, a rate which would carry it nearly eight times round and round the earth in that time; and yet if we take the star which, so far as we know, is our nearest neighbour, it would take three or four years for light from that star to reach the earth. Now, as we see the fixed stars there must be some link of connection between us and them in order that we should be able to perceive them. Probably all of you know that two theories have been put forward as to the nature of light, as to the nature accordingly of that connection of which I have spoken. According to one idea, light is a substance darted forth from the luminous body with an amazing velocity; according to the other, it consists in a change of state taking place, propagated through a medium, as it is called, intervening between the body from which the light proceeds and the eye of the observer. For a considerable time the first of these theories was that chiefly adopted by scientific men. It was that, as you know, which Newton himself adopted; and probably the *prestige* of his name had much to do with the favourable reception which for a long time it received. But more recent researches have so completely established the truth of the other view, and refuted the old doctrine of emissions, that it is now universally held by scientific men that light consists in an undulatory movement propagated in a medium existing in all the space through which light is capable of passing.

This necessity for filling all space, or, at least, such an inconceivably great extent of space, with a medium, the office of which, so far as was known in the first instance, was simply that of propagating light, was an obstacle for a time to the reception by the minds of some of the theory of undulations. Men had been in the habit of regarding the inter-planetary and inter-stellar space as a vacuum, and it seemed too great an assumption to fill all this supposed vacuous space with some kind of medium for the sole purpose of transmitting light. Notwithstanding, even long ago strong opinions were entertained to the effect that there must be something intervening between the different heavenly bodies. In a letter to Bentley, Newton expresses himself in very strong language to this effect: "That gravity should be innate, inherent, and essential to matter, so that one body may act upon another at a distance through a *vacuum*, without the mediation of anything else, by and through which their action and force may be conveyed from one to another, is to me so great an absurdity that I believe that no man who has in philosophical matters a competent faculty of thinking, can ever fall into it. Gravity must be caused by an agent acting constantly according to certain fixed laws; but whether this agent be material or immaterial, I have left to the consideration of my readers."

What the nature of the connection between the earth and the sun, for example, may be whereby the sun is able to attract the earth and thereby keep it in its orbit—in other words, what the cause of gravitation may be—we do not know; for anything we know to the contrary, it may be connected with this intermediate medium or luminiferous ether. There are other offices, we believe, which this luminiferous ether fulfils, to which I shall have occasion to allude presently.

In connection with the necessity for filling such vast regions of space with this medium, a curious question naturally presents itself. We cannot conceive of space as other than infinite, but we habitually think of matter as occupying here or there limited portions of space, as, for example, the different heavenly bodies. The intervening space we commonly think of as a vacuum, and it is only the phenomena of light that led us in the first instance to think of it as filled with some kind of material. The question naturally presents itself to the mind—is this ether absolutely infinite like space? This is a question to which science can give no answer. Though we cannot help thinking of space as infinite, yet when we turn our thoughts to some material existing in space perhaps we more readily think of it as finite than infinite. But if the ether, however vast the portion of space over which it extends, be really limited, we can hardly fail to speculate what there may be outside its limits. Space there might be wholly vacuous, or possibly outside altogether this vast system of stars and ether there may be another system subject to the same laws, or subject to different laws, as the case may be, equally vast in extent; and if there be, then so far as we can gather from such phenomena as are open to our investigation, there can be no communication between that vast portion of space in part of which we live and an ideal system altogether outside the ether of which we have been speaking.

But the properties of the ether are no less remarkable than its vast or even possibly limitless extent. Matter of which our senses give us any cognisance is heavy, that is to say, it gravitates towards other matter which agrees with it in so far as being accessible to our senses. The question presents itself to the mind, does the other gravitate towards what we call ponderable matter? This is a question to which we are not able to give any positive scientific answer. If the ether be in some way or other connected with the cause of gravitation, it would seem more likely that it itself does not gravitate towards ponderable matter.

Again, we have very strong reason for believing that ponderable matter consists of ultimate molecules. First, that supposition accords in the simplest way with the laws of crystallography. Chemical laws afford still stronger confirmation of the hypothesis, through the atomic theory of Dalton, now universally accepted. Comparatively recently, the deduction of the fundamental property of gases from the kinetic theory, as it is called, affords strong additional confirmation of that view of the constitution of matter. Still more recently, the explanation which has been afforded by that theory of that most remarkable instrument, the radiometer of Crookes, has lent further confirmation in the same direction. None of these evidences apply to the ether, and accordingly we are left in doubt whether it too consists of ultimate molecules, or whether, on the other hand, it is continuous, as we cannot help conceiving space to be.

The undulatory theory of light was greatly promoted in the first instance by the known phenomena of sound, and the explanation which they received from the hydrodynamical theory. Accordingly, since sound, as we know, consists of an undulatory movement propagated through the air (or it may be through other media), and depending upon condensation and rarefraction, it was supposed naturally that light was propagated in a similar manner, by virtue of the forces brought into play by the condensation and rarefraction of the ether. But there is one whole class of phenomena which have actually no counterpart in those of sound; I refer to polarisation and double refraction.

The evidence for the truth of the theory of undulations as regards the phenomena of common light depends in great measure upon the fact of interference and the explanation which the theory gives of the complicated phenomena of diffraction. But in studying the interference of polarised light, additional phenomena presented themselves which ultimately pointed out that the vibrations with which we are concerned in the case of the ether, differ altogether in their character from those which belong to sound. The phenomena of the interference of polarised light prove incontestably that there exists in light an element of some kind having relation to directions transverse to that of propagation, and admitting of composition and resolution in a plane perpendicular to the direction of transmission according to the very same laws as those of the composition and resolution of forces, or velocities, or displacements in such a plane. This requires us to attribute to the ether a constitution altogether different from that of air. It points out the existence of a sort of elasticity whereby the ether tends to check the gliding of one layer over another. Have we no example of such a force in the case of ponderable matter? We have. We know that an elastic solid, which for simplicity I will suppose to be uncrystalline, and alike in all directions, has two kinds of elasticity, by one of which it, like air, tends to resist compression and rarefraction; while by the other it tends to resist a continuous gliding of one portion over another, and to restore itself to its primitive state if such a gliding has taken place. There is no direct relation between the magnitude of these two kinds of elasticity, and in the case of an elastic solid, such as jelly, the resistance to compression is enormously great, compared to the resistance to a gliding displacement.

If we assume that in the ether there is really an elasticity tending to restore it to its primitive condition when one layer tends to

* Presidential Address by Sir G. C. Stokes, delivered before the Victoria Institute.

Digitized by Google

glide over another, an elasticity which it appears to be absolutely necessary to admit in order to account for the observed laws of interference of polarised light, the question arises, Can we thereby explain double refraction?

The earliest attempts to explain it in accordance with the theory of transverse vibrations were made by attributing to the ether a molecular constitution more or less analogous to that which we believe to exist in ponderable matter. Following out speculations founded upon that view, the celebrated Fresnel was led to the discovery of the actual laws of double refraction; the theory, however, which he gave was by no means complete, inasmuch as the results were not rigorously deduced from the premises. Cauchy and Neumann, independently and about simultaneously, took up Fresnel's view of the constitution of the ether, and applied it to explain the laws of double refraction. In their theory the conclusions arrived at were rigorously derived from the premises; but the results did not altogether agree with observation—that is to say, although they could by the adoption of certain suppositions be forced into a near accordance with the observed laws of double refraction, yet they pointed out the necessity of the existence of other phenomena which were belied by observation. Our own countryman, Green, was the first to deduce Fresnel's laws from a rigorous dynamical theory, although nearly simultaneously MacCullagh arrived at a theory in some respects similar, though on the whole I think less satisfactory.

Still all these theories followed pretty closely the analogy of ponderable matter; and at least in the first three mentioned the ether was even imagined to consist of discrete molecules, acting on one another like the bodies of the solar system regarded as points, by forces in the direction of the joining line, and varying as some function of the distance. I have already quoted the very strong language in which Newton rejected the idea of the heavenly bodies acting on one another across intervening spaces which were absolutely void. But the conception has nothing to do with the magnitude of the intervening spaces; and the conception of action at a distance across an intervening space which is absolutely void, is not a bit easier when the space in question is merely that separating two adjacent molecules, when the ether is thought of as consisting of discrete molecules, than it is when the space is that separating two bodies of the solar system, though in this latter case it may amount to many millions of miles. If the ether be in some unknown manner the link of connection whereby two heavenly bodies are enabled to exert on one another the attraction of gravitation, then, according to the hypothetical constitution of the ether that we have been considering, we seem compelled to invent an ether of the second order, so to speak, to form a link of connection between two separate molecules of the luminiferous ether. But since the nature of the ether is so very different, as it must be, from that of ponderable matter, it may be that the true theory must proceed upon lines in which our previous conceptions, derived from the study of ponderable matter, are in great measure departed from.

If we think of the ether as a sort of gigantic jelly, we can hardly imagine but that it would more or less resist the passage of the heavenly bodies—the planets for instance—through it. Yet there appears to be no certain indication of any such resistance. It has been observed indeed in the case of Encke's comet, that at successive revolutions the comet returned to its perihelion a little before the calculated time. This would be accounted for by the supposition that it experienced a certain amount of resistance from the ether. Although at first sight we might be disposed to say that such a resistance would retard perihelion passage, yet the fact that it would accelerate it becomes easily intelligible, if we consider that the resistance experienced would tend to check its motion, and so prevent it from getting away so far from the sun at aphelion, and would consequently bring it more nearly into the condition of a planet circulating round the sun in a smaller orbit.

Many years ago I asked the highest authority in this country on physical astronomy, the late Prof. Adams, what he thought of the evidence afforded by Encke's comet for the existence of a retarding force, such as might arise from the ether. He said to me that he thought we did not know enough as to whether there might not possibly be a planet or planets within the orbit of Mercury which would account for it in a different way. But quite independently of such a supposition, it is worthy of note that the remarkable phenomena presented by the tails of comets render it by no means unlikely that even without the presence of a resisting medium, and without the disturbing force arising from the attraction of an unknown planet situated so near to the sun as not to have been seen hitherto, the motion of the head of a comet might not be quite the same as that of a simple body representing the nucleus, and being subject to the gravitation of the sun and planets and nothing else. It appears that the tails consist of some kind of matter driven from the comet with an enormous velocity by a sort of repulsion emanating from the sun. If the nucleus loses in this manner at each perihelion passage an exceedingly small portion of its mass, which is repelled from the sun, it is possible that the residue may experience an attraction towards the sun over and above that due to gravitation, and that possibly this may be the cause of the observed acceleration in the time of passing perihelion even though there be no resistance on the part of the ether. So that the question of resistance or no resistance must be left an open one.

The supposition that the ether would resist in this manner a body moving through it is derived from what we observe in the case of solids moving through fluids, liquid or gaseous, as the case may be. In ordinary cases of resistance, the main representative of the work apparently lost in propelling the solid is in the first instance the molecular kinetic energy of the trail of eddies in the wake. The formation of these eddies is, however, an indirect effect of the internal friction, or if we prefer the term viscosity, of the fluid. Now the viscosity of gases has been explained on the kinetic theory of gases, and in the case of a liquid we cannot well doubt that it is connected with the constitution of the substance as not being absolutely continuous but molecular. But if the ether be either non-molecular or molecular in some totally different sense from ponderable matter, we cannot with safety infer that the motion of a solid through it necessarily implies resistance.

The luminiferous ether touches on another mysterious agent, the nature of which is unknown, although its laws are in many respects known, and it is applied to the every-day wants of life, and its applications are even regulated by Acts of Parliament; I allude to electricity. I said that the nature of electricity is unknown. More than forty years ago I was sitting at dinner beside the illustrious Faraday, and I said to him that I thought a great step would have been made if we could say of electricity something analogous to what we say of light, when we affirm that light consists of undulations; and he said to me that he thought we were a long way off that at present. But, as I said, relations have recently been discovered between light and electricity which lead us to believe that the latter is most closely connected with the luminiferous ether.

Clerk-Maxwell showed that the ratio of two electrical constants which are capable of being determined by laboratory experiments, and which are of such a nature that that ratio expresses a velocity, agrees with remarkable accuracy with the known velocity of light. This formed the starting-point of the electromagnetic theory of light which is so closely associated with the name of Maxwell.

According to this idea, light may be looked on as the propagation of an electromagnetic disturbance, whatever the appropriate idea of such a thing may actually be. The theory has quite recently received remarkable confirmation by the investigations of Hertz, who has shown that what are incontestably electromagnetic disturbances, and are investigated by purely electrical means, exhibit some of the fundamental phenomena of light, such, for example, as interference and polarisation. It appears that these electromagnetic waves are strictly of a similar nature to the waves of light, though there is an enormous difference in the scale of wave-lengths, which in the case of light range about the one-fifty thousandth part of an inch, while the electromagnetic waves which have been investigated by purely electrical methods range from a few inches to many yards.

The Prevention of Sparking.—A recent number of *L'Electricien* describes some of the means which may be adopted for diminishing sparking at the brushes of continuous current dynamos. The first instalment of this article deals only with closed-coil armatures. The writer, M. Rechniewsky, asserts that in the best of dynamos of this class it is necessary to shift the brushes in order to prevent sparking when the current varies. This, however, is only correct as far as it relates to continuous current dynamos such as are to be found in our best central stations when the variation of current is very large indeed; for moderate variations the change in the resulting field and the alteration of lead are negligible. The writer illustrates what may be supposed to take place in a general way when an armature section is commutated, by means of a series of diagrams dealing with the three cases of—too early, too late, and non-sparking commutation. These diagrams, which are far from representing the details of what actually takes place in the commutated section, are, nevertheless, likely to assist a student in getting at the main idea correctly. The latter portion of the first instalment discusses the question of sparking from the dynamo characteristic point of view, and compares the effect of a given change of current in a Pacinotti-wound armature with that in the armatures without projecting teeth.

ON THE TRANSPARENCY OF EBONITE.*

BY RICCARDO ARNÒ.

The transmitting power of thin sheets of ebonite was determined for heat rays due to six different sources, by means of a thermopile and a Thomson astatic mirror galvanometer. The sources were :— 1. An incandescent lamp fed by a battery of accumulators, with the interposition of a plate of ordinary glass 7 mm. thick. 2. The same incandescent lamp without the glass plate. 3. A Locatelli lamp. 4. A spiral of platinum made incandescent by means of a Bunsen burner. 5. An iron plate heated by an alcohol lamp. 6. The smoked face of a Leslie cube containing boiling water.

Three films of ebonite were experimented upon, two of them with a bright surface, and thicknesses 0·12mm. and 0·52mm. respectively, and a third 0·44mm. thick, with a dull surface. Calling 100 the amount of heat given out by each source, the amounts transmitted are given by the following table :—

Thickness of ebonite film. mm.	Diathermanous power for the different sources.					
	1.	2.	3.	4.	5.	6.
0·12	75	68	62	54	43	31
0·52	62	51	40	30	21	12
0·44	44	37	30	23	17	12

These data lead to the following conclusions :—

1. Ebonite in thin films is not equally transparent for all the radiations of obscure heat.

2. Its transparency for such radiations increases with their refrangibility and is greatest for those of smallest wave length. Its diathermanous power is, in fact, greatest when the source of heat (in these experiments an incandescent lamp screened by a glass plate) is one that sends out heat radiations for the most part of small wave-length. It must here be remarked that, if the film is thin enough, it is also transparent as regards the less refrangible luminous rays, as was verified for the specimen of thickness 0·12mm., across which red light was able to pass when the source was very bright.

3. Ebonite is nearly opaque for heat radiations of low refrangibility, such as those of the smoked face of a Leslie cube at 100deg.

4. As in the case of other diathermanous bodies, the transmitting power of ebonite increases as the brightness of the surfaces increases or the thickness diminishes.

According to Maxwell's electromagnetic theory of light we must, therefore, hold that ebonite, which is a bad conductor for continuous currents, for ordinary alternating currents, and for alternating currents of a frequency equal to that of Hertzian electromagnetic oscillations, is conducting for electromagnetic oscillations having a frequency of the order of magnitude of those corresponding to obscure heat radiations of great wave length, and again acquires the properties of dielectric bodies for obscure oscillations of wave-length nearest to that of red light, to become finally again a good conductor for luminous oscillations.

* From the Atti della R. Accademia delle Scienze di Torino, June, 1893.

THE UNIVERSAL DYNAMO.

Teachers of technical electricity who are desirous that their laboratories shall attain a maximum of efficiency and scope, notwithstanding the tendency of funds towards a microscopic minimum, must sometimes be at almost their wits' ends because of the increasing multiplicity of machinery used in modern electrical engineering. To take a single instance, how many are the forms and functions of the class of machines known as the dynamo! Series dynamos, shunt-dynamos, compounded, over-compounded, under-compounded, separately excited, alternating, two-phase, and many other types of dynamos exist. And a large fund must be voted from the exchequer if each and every one is to be separately represented in the students' laboratory, together with all the principal types of other things.

But the principle of *multum in parvo* often solves the difficulty, and places at the Professor's disposal a single machine which is warranted to do everything that all other machines put together can do. Some such machine we find in the Universal Dynamo, manufactured by Messrs. E. H. Cadiot and Co., of Paris, which, by an ingenious arrangement of plug switches and binding posts, can be variously modified so as to become any one of the different kinds of dynamos we have named. The general form of the machine is shown in Fig. 1 ; and in Fig. 2 is represented the usual arrangement of driving gear by means of which it may be worked by 2-student-power, while the other students are making the tests. In another form the support is mounted on small wheels and provided with handles, like a lawn mower, so that it can readily be trundled about.

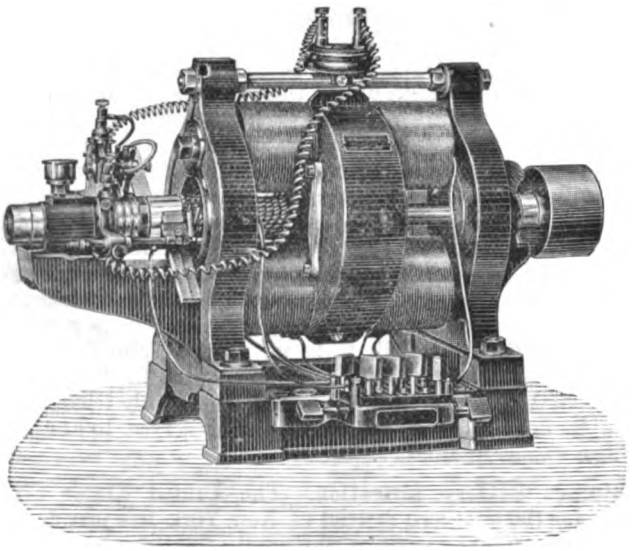

FIG. 1.

A "practical man" may have his objections to a dynamo which by means of a plug or two can be transformed from an alternator into a compound dynamo for constant voltage ; but in a student's dynamo these objections do not count. Efficiency is no object—

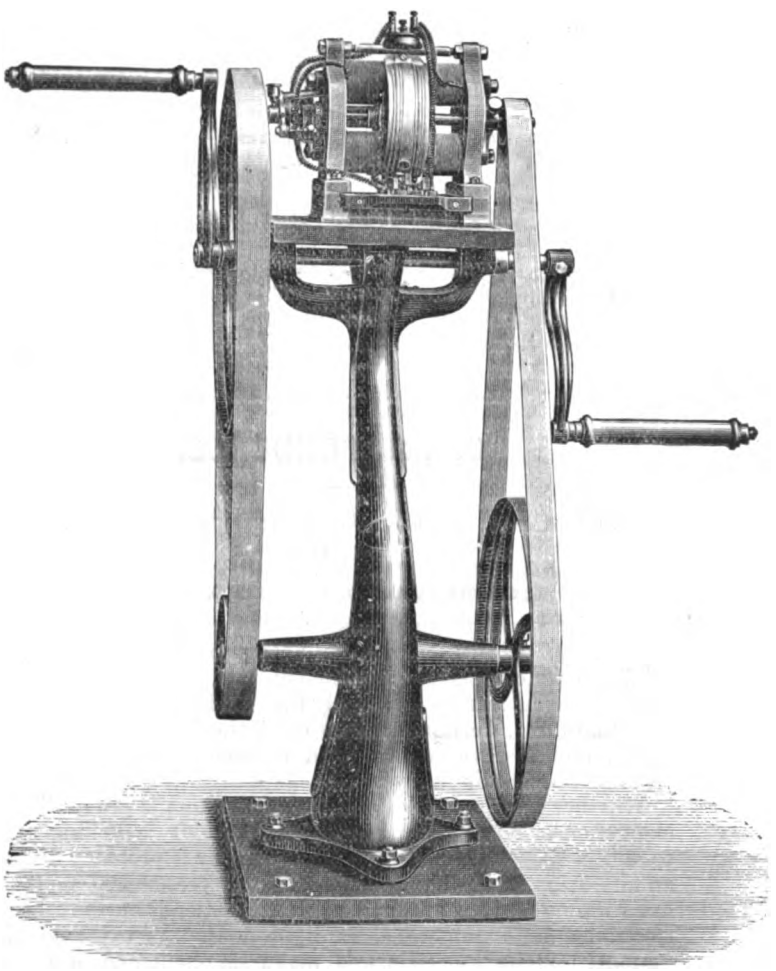

FIG. 2.

unless to the man who is grinding away at the handles. Indeed, a bad dynamo is often the most instructive one, and inefficiency often brings out useful truths almost in proportion as it wastes useful energy.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 22, 1893.

Incandescent Lamp Litigation.—On July 20th the United States Court at Milwaukee, Wis., handed down a decision granting an injunction against the Oconto Lamp Company. The defence in this case, like in those at Boston and St. Louis, was what is known as the "Goebel defence." It will be remembered that the St. Louis court in the case of the Columbia Company considered this defence strong enough to justify it in refusing to grant a preliminary injunction in favour of the Edison lamp, while the Boston court decided the reverse. There is thus one decision sustaining the Goebel defence and two decisions against it. The impression seems to prevail that this is the last of one of the most remarkable defences ever presented before a court. There is a rumour that the next defence will be based upon a claim for priority for Swan as the inventor of the incandescent lamp. It is stated that this case has never been thoroughly tried, having gone by default in one case abroad and served to annul the Edison patent in another.

Storage Battery Litigation.—The United States Circuit Court for the southern district of New York has just declared the famous Faure patent on the application of active material in the form of paste, paint or cement, to have lapsed and expired by reason of the prior expiration of the Faure Spanish patent for the same invention. This seems to leave the field clear for the licences of the Brush Company, whose fundamental patent on the use of a metallic support for the active material has been sustained by the courts. The long litigation in the United States on various storage battery patents has had a very depressing effect on that industry, and the outlook for the future seems none too bright on account of the restriction in regard to the use of a metallic support.

The International Electrical Congress.—It is probable that the subject of a millimetre wire gauge may come before the Chicago Congress, and a determined effort will be made to have the Congress express an opinion in regard to the definition of the candle-power of arc lamps in terms of watts; it is not thought that the Congress can take any formal action on this latter question, but it is hoped to have it favoured by at least informal action, which will, it is thought, be sufficient to influence the electrical public.

CORRESPONDENCE.

VELOCITY OF GRAVITY AND A RESISTING MEDIUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To avoid misapprehension, will you allow me to explain that when I pointed out that an aberrational effect of gravity might partly compensate for the effect of a resisting medium, I by no means intended to imply that I believed in these things as actualities. Certainly if they exist they must be extremely small, and I have several good reasons for believing that etherial viscosity is really *nil*.

Whether it be so or not, and whether there is gravitational aberration or not, I never contemplated gravity travelling with so slow a speed as that of light. Gravity is probably due to an alteration of the ether caused by the presence of matter; but I see no reason for supposing that it depends on the ether's electromagnetic properties, as light does. As expressed in "Modern Views," electric and magnetic phenomena are concerned with a shearing of the ether, a displacement or motion of its constituent parts in opposite directions; whereas gravity is probably due to an effect taking place in the ether as a whole.

If the ether is really incompressible, as it appears to be, then gravity need not *travel* at all, but simply *exists* throughout space round every material lump. This is what I think most likely.

It may be interesting to note that if gravity is caused by a stress analogous to a Maxwell stress, the etherial tension near the earth is 600,000 atmospheres, and near the sun 10,000 times as great; but that the stress produced by the sun over here is less than three atmospheres. Good steel can only stand 10,000 atmospheres' tension, or one-sixtieth of the terrestrial gravitational stress. The ether is no inferior sort of material. It would appear to be not only infinite in size but in other properties also.

At the same time the etherial stress caused by an ordinary lump of matter is excessively minute; it would need a globe of water 100 yards in diameter, for instance, to cause a stress of 1 dyne per square centimetre, or one-millionth of an atmosphere; and the stress caused by a vortex atom (always on the Maxwell-stress-hypothesis of gravity) is 10^{-23} of a dyne per square centimetre. This is all the residual effect which our hydro dynamic vorticians have to account for in order to explain gravity.—Yours, &c., OLIVER J. LODGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: After reading Dr. Lodge's interesting letter in *The Electrician* of July 28th, it seemed to me that it might not be out of place to record a few considerations suggested by the same. They are not objections to the theory given; but are intended to draw from him or from others some further discussion of the matter.

(1.) If the planet be "kept going" in spite of viscous friction, then work is being done upon it; and we must look for a disappearance of some other form of energy at an equivalent rate.

(2.) If I have not misunderstood the meaning of "lag," I imagine that it is assumed that, if there be such lag, the planet experiences at any moment a force which is the same in magnitude and direction as that which, if there were no lag, it would have experienced at some previous moment. Some suggestion as to the physical explanation of this would be instructive.

(3.) If the above view as to the meaning of "lag" be correct, then in the case of a body approaching the sun the gravitational stress between them would be at each moment *less* than if the two bodies had been at rest; and, if moving away from the sun, it would be *greater*. A lag in gravitation would then act *with* viscosity as regards perturbations of comets moving in hyperbolic paths, over the greater part of their paths.

(4.) And, perhaps, similar reasoning would, in the case of elliptic orbits, account for the changes in the ellipse, which are of such importance in what may be called the "Theory of Ice Ages."

It will be seen that in (3) and (4) attention is drawn to the fact that there would be lag in magnitude as well as lag in direction of the gravitational pull.—Yours, &c.,

W. LARDEN.

THE PARSONS STEAM TURBINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your comments on Prof. Kennedy's recent trials of the Parsons steam turbine (July 21st, p. 303), the reference to my own earlier trials contains an error that is worth correcting. Speaking of the tests made by me last August, in which superheated steam was used, you give 27.6 lb. as the recorded consumption of feed-water per electrical horse-power hour, whereas in fact it was 27·7lb. per *Board of Trade electrical unit*, or kilowatt hour. Prof. Kennedy's trials make the consumption slightly less than this, but the main improvement which they record is the augmented output from a machine of the same size. In this respect it appears that Mr. Parsons has bettered even his remarkable achievement of a year ago by something like 50 per cent.; and Prof. Kennedy's figures show, by comparison with mine, that this great increase in power has been secured without loss—

Digitized by Google

indeed, with some gain—in efficiency. That there may be no mistake I put the figures side by side:—

Tests of Parsons Steam Turbine and Dynamo.

—	Rate of output during the test.	Consumption of feed-water. Per E.H.P hour.	Per B.T.U.
	kilowatts.	lb.	lb.
Ewing: August, 1892.			
(1) Steam at pressure of 103lb. in boiler, superheated 58°F.....	102	21·2	28·4
(2) Steam at pressure of 101lb. in boiler, superheated 127°F.	78	20·7	27·7
Kennedy: May, 1893.			
Steam at pressure of 97lb. in boiler, superheated 55 F.....	123	20·3	27·2

It will be seen from this table that with the same moderate degree of superheating as Prof. Kennedy used, I found the consumption of feed-water to be 21·2lb. per electrical horse-power hour, while in his test, with the machine altered to give a larger output, the consumption of feed-water was reduced to 20·3lb. which is 4 per cent. less. Neither in Prof. Kennedy's tests nor in mine was any deduction made from the measured amount of feed-water on account of boiler leakage, although it was known that some leakage was taking place—a fact which, of course, emphasises these very striking results. As Prof. Kennedy justly says, they rank among the best hitherto obtained in the direct driving of dynamos by condensing machinery.—Yours, &c.,

J. A. Ewing.

Cambridge, July 29, 1893.

LEGAL INTELLIGENCE.

Addison and Others v. Ness.

On Thursday this case came before the House of Lords by way of appeal from a judgement of the Court of Appeal, reversing a judgment of Mr. Justice Kekewich.

The question depended on the construction of an agreement made between the promotors of the Oriental Telephone Company (Limited) and the Company itself, which was incorporated in 1881 with a nominal capital of £300,000 in shares of £1 each. The promoters were to receive a certain number of shares, fully paid up, as part satisfaction of the purchase money payable to them, called "Vendor's shares," the rest of the shares being Ordinary shares. It was part of the agreement that during the first five years of the Company's existence the holders of the Vendor's shares should not participate in the profits of the Company until the holders of the Ordinary shares should have been paid a dividend of 6 per cent. per annum. Then the holders of the Vendor's shares were to receive 6 per cent. on their shares, and the balance was to be applied in paying dividends on all the shares, *pari passu*, in proportion to the amount paid up. Any deficiency in the dividends on the Ordinary shares was to be made up out of the profits of the Company in future years, in priority to the rights of the Vendors to participate in them. At the end of the first five years there was a deficiency amounting to £20,000, and the question was, how the dividends of the Company were to be dealt with after the period of five years. The holders of the Ordinary shares contended that they were then entitled to receive their rateable dividend out of the profits, and to have the balance of those profits applied to the making up of the deficiency on their dividends during the first five years in priority to the rights of the holders of the Vendors' shares to participate in profits; while the holders of the Vendors' shares held, on the other hand, that until the deficiency was made up the holders of the Ordinary shares were no more entitled to dividends than they were, and that the whole of the profits applicable to the payment of dividends must be applied preferentially in or towards making up the deficiency.

Mr. Justice Kekewich decided in favour of the contention of the appellants, who represented the Ordinary shareholders; but his decision was reversed by the Court of Appeal.

Lords Halsbury, Watson, and Macnaghton were of opinion that the judgment of the Court of Appeal should be reversed, and the judgment of Mr. Justice Kekewich restored, Lords Morris and Shand dissenting.

The judgment of the Court of Appeal was reversed, and the respondent ordered to pay the costs.

Consolidated Telephone Construction and Maintenance Company (Limited).

Application was made on Saturday to Mr. Justice Stirling by Mr. Buckley, Q.C., for power to reduce the capital of this Company. He stated that in consequence of the taking over of the Telephone Company of Austria, in which this Company held shares, by the Austrian Government, a sum of about £50,000 had been set free, and part of this sum of was proposed to utilise by paying off the Preference shares of £1 each, which would absorb £22,400. Then, on account of the running out its several of the patents under which the Company worked, there had been a depreciation in the assets of the Company which the Directors estimated to be not less than £24,000, and they desired to write off 2s. per share on the Ordinary shares on account of loss.

His LORDSHIP made the necessary order, remarking that it was merely a return of capital in excess of the requirements of the Company.

Hutchinson v. Gill.

This action, which came before the West Riding Summer Assizes last week, was brought by Mr. W. B. Hutchinson, electrical engineer of Liversedge, to recover damages for slander against Mr. J. Gill, a member of the Heckmondwike Local Board. The alleged slander was uttered in connection with the appointment of an electrical engineer by the Local Board, and in the result a verdict for the plaintiff with costs, according to agreement, was assented to by both parties, and the jury found accordingly.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Tenders Invited.—The Cheshunt Local Board invite tenders for the public lighting of their district by gas, oil, or otherwise. Specifications may be seen at the Surveyor's office, and tenders must be in by Monday next.

——— The Technical Instruction Committee of the York Town Council invite tenders for the wiring of the Institute in Clifford-street for the electric light. Specifications, forms of tender, &c., can be obtained from Mr. A. Creer, the city engineer, to whom tenders must be delivered by noon on Tuesday, August 15th. Further particulars appear in our advertisement columns.

——— The Committee of the Derby Public Library Museum and Art Gallery invite tenders for the wiring of their buildings, and for the supply of fittings and accessories. Tenders must be in by the 9th instant.

——— The Gateshead Industrial Co-operative Society (Limited) propose to instal the electric light in their Jackson-street premises, tenders for which must be in by Saturday, the 12th instant.

Tenders Accepted.—The Yorkshire House-to-House Electricity Company (Limited) have accepted the tenders of Messrs. W. Nicholson and Co., of Hunslet, Leeds, for the builders' work, and of Messrs. John Fowler and Co., Leeds (Limited), for the engines, dynamos, &c., for the extension of their works at Leeds.

——— The Gas and Lighting Committee of the Bolton Corporation have accepted the tender of Messrs. Hick, Hargreaves, and Co. for the supply of the steam boilers for the central electric light station, but have deferred the acceptance of tenders for engines and for the erection of the building.

——— The Hampstead Vestry on Thursday last week had under consideration the report of the Electric Light Committee upon the tenders received for erecting buildings for the central electric light station, and for the supply of the plant. The Committee recommended the acceptance of the tender of Messrs. R. A. Yerbury and Sons, of Kilburn, for the erection of the chimney shaft and buildings at £7,350, and that of Messrs. Siemens. Bros. and Co. (Limited) for the plant, mains, &c., at £19,794; and the Vestry adopted both recommendations after some discussion. Thirty-one tenders were received for the supply of portions of the plant, and the following were from firms wishing to supply the whole of the machinery, &c.:—

Brush Electrical Engineering Company (Limited)	£22,047
Messrs. Latimer Clark, Muirhead and Co. (Limited)	21,850
" " " (alternative tender)	21,129
Messrs. Sharp and Kent	21,572
Messrs. Crompton and Co. (Limited)	21,512
Electric Construction Company (Limited)	21,232
Messrs. Siemens Bros. and Co. (Limited)	19,914
" " " (alternative tender)	19,120

Messrs. Siemens Brothers and Co.'s tender of £19,914 was accepted, as stated above, subject to a deduction of £120.

——— The Lighting and Electrical Committee of the Cardiff Corporation have decided to recommend the Council to accept the tender of Messrs. Siemens Bros. and Co. (Limited) for the supply of arc lamps, and that of Messrs. W. C. Hampton and Co. for the supply of cast-iron pipes for the underground cables.

Sales by Auction.—Messrs. Wheatley Kirk, Price and Goulty announce important sales of electrical stock, stores, dynamos, instruments, and engineering plant and machinery *in re* Blakey, Emmott and Co., Limited (in liquidation). The sale will take place at an early date, and includes the entire stock and contents of the works at Halifax. Catalogues will shortly be ready, and all further particulars can be obtained from the auctioneers, 49, Queen Victoria-street, E.C., and Albert-square, Manchester.

Digitized by Google

APPOINTMENTS VACANT.—The Hove Commissioners advertise for an electrical engineering assistant, competent to supervise the construction of culverts, the laying of electric light mains, and the erection of electrical plant and generating machinery for the lighting supply of Hove (Sussex). Applications must be sent in to the Town Clerk, the Town Hall, Hove, not later than the 9th inst. Some further particulars are given in our advertisement columns.

——— The Government of India requires a mechanical engineer to take charge of the telegraph department workshops at Calcutta. The appointment is on a five year's agreement, and the salary is Rs.850 per mensem, rising by increments to Rs.1,000 per mensem. Further particulars appear in our advertisement columns, and applications must reach the Secretary, Public Works Department, India Office, S.W., not later than 31st inst.

MESSRS. PATERSON AND COOPER.—We are informed that Mr. W. C. Martin has ceased his connection with Messrs. Paterson and Cooper as manager of their Glasgow branch ; and that Mr. E. Geo. Tidd has been appointed in his place.

MESSRS. W. T. GOOLDEN AND CO.—This firm announce that their works and offices will be closed for the annual holidays from August 28th to September 2nd, inclusive.

STEAM SAVING APPLIANCES. — The Chadderton Iron Works Company send us their new catalogue of M'Dougal's patent steam saving appliances, several of which are illustrated and described in the pamphlet. The Company's specialities include patent steam traps for any variation of pressure, combined steam dryers and water and dirt separators, anti-primers, mechanical stokers, sight feed lubricators, &c.

MESSRS. JULIUS SAX AND CO.—The Court of Common Council have resolved to grant this firm the building lease of land in Charterhouse-street on which to erect a lighting station for the markets, at £500 per annum, the Court to pay £6,000 in the event of their requiring the land before the expiry of the lease, for any buildings thereon.

FOWLER-WARING CABLES COMPANY (LIMITED).—A very attractive and interesting illustrated and descriptive catalogue has just been issued by this firm. The work comprises a number of coloured illustrations of cables for electric lighting, telephonic and telegraphic purposes, and of junction boxes, fittings, tools, &c. In the lead-covered cables, for which the Company enjoy a well-earned reputation, the difficulties first experienced have, in a great measure, been overcome, and this type of cable is now being extensively adopted. In the section of the catalogue which deals with concentric wiring we find fully illustrated descriptions of junctions, switch-boxes, &c., specially adapted to the lead-covered and "dry-core" cables manufactured by the firm. A brief description is given of the methods and materials employed in the manufacture of the Fowler-Waring cables, written by Mr. A. E. Mavor, the General Manager. Testimonials are included from Lord Kelvin, Sir Frederick Bramwell, Mr. Preece, and others. A variety of useful tables, instructions for laying and jointing, and a telegraph code for ordering, add to the value of the publication. In this era of well-arranged and carefully-compiled catalogues the book under notice certainly takes front rank.

MESSRS. C. A. PARSONS AND CO.—The new catalogue and price list of this firm contains, in its introduction, much useful information. The cost of construction and maintenance of the Cambridge and the Newcastle central stations are discussed ; and several large illustrations of these stations, and of details of the plant, are given. The catalogue gives price lists of the Parsons steam turbines, dynamos and alternators, and of sundry auxiliary details, and includes useful tables of the dimensions and performances of the Parsons engines.

"FIBERITE."—We have received from Messrs. Shippey Bros. some specimens of "fiberite," which is stated to be "a new compound material for incandescent lamp filaments," and which can be pressed into sheets or drawn into very fine threads as required.

BANDON.—A public meeting of the ratepayers was held on Monday when a resolution was adopted, calling on the Town Commissioners not to give their consent to the proposed application by the Bandon Electric Lighting Company (Limited) for a Provisional Order.

BANK HOLIDAY ARRANGEMENTS.—The Post Office authorities issue a special circular relating to the arrangements for postings, parcel posts, and express delivery for Monday, August 7th, which can be obtained of any district, or sub-office.

CLEATOR MOOR.—The Co-operative Society have instructed Mr. Watson Bell, of Whitehaven, to instal the electric light in their mill and warehouse. The plant to be supplied will be capable of supplying current for lighting the central stores, if this should be deemed advisable.

COVENTRY.—At the meeting of the Town Council on Tuesday, the Electric Light Committee recommended that they be empowered to employ a consulting engineer, but it was decided that before this was done the Committee should present a report of their investigations, so far as they had proceeded.

DOWNPATRICK.—At a special meeting of the Town Commissioners, on Friday, to consider the lighting of the extended town boundary, it was resolved that unless arrangements could be come to with the gas company some other means of lighting should be adopted.

EDINBURGH.—At the meeting on Monday of the Edinburgh and Leith Corporation's Gas Commissioners, a letter was read from the Town Clerk of Edinburgh asking if the Commissioners would be willing to supply the Corporation with gas for their engines to be used in the production of the electric light at the same rate as they did at present for public lighting. The letter pointed out that the price at which the gas would be supplied would be an important factor in arriving at a decision whether gas or steam engines would be used. In the discussion which followed, objection was raised to the gas being supplied at a lower rate than was charged for private lighting, as it was argued that the City would be supplying the electric light to the Commissioner's best customers, and the latter would, therefore, be simply cutting their own throats by supplying gas so cheaply for producing the electric light. The matter was ultimately remitted to the Works Committee for consideration, and the Gas Commission will hold a special meeting on the 14th inst. to settle the question.

FLEETWOOD.—The Special Committee of the Local Board who are considering the question of the electric light are visiting various central stations in order to obtain information.

HASWELL (DURHAM).—It has been decided to light the premises of the Haswell Co-operative Society by electricity.

GLASGOW.—The applications for the supply of the electric light are so numerous that it is evident the present plant will soon become inadequate to meet the demand, and the Town Council have remitted to a sub-committee the consideration of a scheme for the extension of the system. It is proposed to remove the dynamos which generate the supply for street lighting from Waterloo-street to the premises in John-street, formerly occupied by Messrs. Mavor and Coulson, and to erect in their place plant for the supply of current for house incandescent lighting.

GREAT GRIMSBY.—At a meeting of the Public Lighting Committee of the Town Council, held last week, the surveyor gave particulars of some replies he had received from other local authorities with reference to street electric lighting. The consideration of the matter was postponed for a month.

HIGH WYCOMBE.—The Town Council at their last meeting decided to take the necessary steps towards obtaining a Provisional Order for the lighting of the town by electricity.

LANCASTER.—The Local Government Board have sanctioned the borrowing by the Corporation of £25,000 for the purpose of electric lighting, respecting which an inquiry was recently held. The Town Council at their last meeting accepted various tenders for the building work in connection with the erection of the central station, and they have fixed the price for the current at 7d. per Board of Trade unit.

LECTURE.—On Friday evening last, Mr. George Offor delivered a lecture on "Electricity as applied to Domestic Purposes," before a large audience at Westwood House, Upper Sydenham, S.E. The lecturer dealt with the importance of the undertaking carried out by the Crystal Palace and District Electric Supply Company, and generally with the subject of the uses of electricity for domestic purposes. Taking the Crystal Palace as a centre, the important residential neighbourhood surrounding it had been included in the Company's area of supply, which extended about two miles from north to south, and 1½ miles from east to west. Between 7 and 8 miles of trenches had been constructed, in which more than 50 miles of cables had been laid, and pilot wires for regulating the pressure, which is delivered at 100 volts. At each sub-station there was a motor dynamo and battery of E.P.S. accumulators of the K type. The lecture was illustrated by a successful exhibition of cooking, ironing, ventilating, cigar-lighting, &c. Mr. Offor concluded by showing the rapid progress of the electric supply industry, and referred to the dividends paid by a large number of metropolitan and provincial companies, as indications of its future success. The first house in the Company's area was connected with the mains in February last, and there were now about 3,000 actually running or being wired.

MANCHESTER.—The Manchester Chamber of Commerce have had under discussion the increasing number of subway constructions for electric and other purposes under the streets of the city, and have resolved that it is essential to the public interest that the Corporation should continue to retain complete control over the public streets, and over communications of all kinds beneath the surface.

PETERBOROUGH.—Prominent tradesmen of this city are pushing forward the electric light. Mr. R. Hammond recently addressed a meeting of the townspeople on the subject and secured an appreciative audience. The Mayor (who presided) said the Corporation had received no request from the townspeople for the electric light.

Digitized by Google

was ultimately decided to memorialise the Town Council to her adopt the electric light or to allow a private company to so.—With reference to the above, the Town Council at their t meeting decided to oppose the application of the Midland ouse-to-House Electricity Company (Limited) for a Provisional der for supplying electricity within the borough, and directed eir engineer to report upon the matter with a view to the rporation themselves erecting a central station.

RUGBY.—The Local Board on Saturday agreed to a request from Rugby School Electric Lighting Company (Limited) that the ard should undertake the task of laying the cast-iron pipes for cables where they crossed the public road, subject to their ng relieved from all subsequent liability.

SHOREDITCH.—The Electric Lighting Committee of the Vestry, he last meeting, reported that they had considered the question the joint purchase of the Pitfield-street site for the purposes of cting an electric light station, free library buildings, and public hs, and recommended the purchase of the site by the Vestry. ong discussion ensued, and was eventually adjourned.

THE ELECTRIC LIGHT IN PRINTING OFFICES.—The offices of the rkshire Post, at Leeds, have been fitted with the electric light, installation consisting of upwards of 400 incandescent lamps l four arc lamps. In the type-composing department, in which re are 200 lights, a specially designed swivel bracket has been roduced, which allows the lamp to be moved over a considerable ce, and is extremely effective for its purpose.

TWICKENHAM.—The Local Board had before them at their last eting a report by the surveyor on the schemes submitted by ssrs. Hammond and Co. for the electric lighting of the district. e annual cost for lighting the areas suggested was estimated at ,840, and (for a much larger area) £5,591. The present cost of street lighting by gas in these areas was £150 and £580 respec-ely, and it followed that some £2,700 or £5,000 would have to be ceived from private lighting to make the scheme pay. After some cussion a decision on the subject was postponed until the Lighting mmittee had ascertained by inquiry whether there was any proba-ity of the requisite number of private consumers taking the current.

WANDSWORTH.—At the last vestry meeting, in reply to a ques-on as to the possibility of the electric light being supplied to strict, Dr. Howell thought it would be a good many years before ectricity would come to Wandsworth. The fact was that all the mpanies that proposed to supply Putney and Wandsworth with ectricity had failed to get the capital to float themselves, and so e matter had fallen through.

WHITEHAVEN.—The Harbour Committee have decided to recom-end the Local Board to light the Harbour by electricity at the tal cost of £220 per annum, on the terms proposed by the Elec-ic Lighting Committee.

WORCESTER.—The Board of Guardians at their meeting on Thurs-ay week had under consideration the question of lighting the new orkhouse by electricity; but after some discussion it was decided postpone the matter.

COMPANIES' MEETINGS AND REPORTS.

The Direct United States Cable Company (Limited).

The thirty-second ordinary general meeting of this Company was held Winchester House, Old Broad-street, on Friday, July 28th, under the residency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. T. Finnis), read the notice convening the meet-ng and the minutes of the last ordinary general meeting, which were pproved by the present meeting and signed by the Chairman as correct. he report of the Directors, which has been published in *The Electrician*, as taken as read.

The CHAIRMAN: Before I move the first resolution I will, as usual, o over the report and give you any further information which I onsider it desirable that you should have. In fact, we give you, as a ule, all the information that we ourselves possess, and we always think hat the more information we can give to our shareholders on an ccasion of this kind, the more it increases that confidence which ought o exist between this side of the table and the other side. The revenue or the half-year to June 30th last, after deducting outpayments, amounted n round figures to £40,837, and the working and other expenses, ncluding income-tax and depreciation, to £18,898, leaving a balance of £21,939, as the net profit of the half-year, making with £3,129 brought orward from the previous year a total of £25,068, which has been appropriated as follows:—Interim dividend of 3s. 6d. per share for the quarter to March 31st £10,624. 5s.; proposed final dividend of 3s. 6d. per share for the quarter to June 30th £10,624. 5s.; transferred to reserve fund £3,000; balance proposed to be carried forward £819. 2s. 4d. The revenue as compared with that in the corresponding period of last year shows an increase of £1,822. This is not a large amount but it is on the right side of the account, and considering the very general depression which has existed, the result must be regarded as satisfactory. The expenses in London, as shown by abstract "A" in the accounts, remain so very nearly the same as in the corresponding period that a comparison of the items is unnecessary. The total shows the small increase of £24. The expenses at stations, as detailed in abstract "B," shows as follows:—Increases of £260 in salaries and wages, £27 in maintenance, £26 in petties, £13 in rent, fuel, and light, £67 in travelling, £50 in printing, and £100 in agencies. At the same time several of the items are slightly reduced. On the whole these expenses show an increase of £490, chiefly due to the new head station at Mark-lane, which was not working in the corresponding period of the previous year, though I referred to it. In the remaining items of expenditure there are reductions of £131 in Directors' remuneration, £69 in law charges, and £476 in freight of cable account, the total of the expenditure in the aggregate showing a saving of £121—not a large sum, but again on the right side of the books. A comparison of the past full year's working to June 30th with that in the corresponding period shows that while our revenue has been more than maintained, our working expenditure, notwithstanding the running of additional stations and new agencies, has only been very slightly increased. The reserve fund, increased by the interest on the investments, £4,117 6s. 6d., and £3,000 transferred from the revenue account, now amounts to £267,415 12s. 7d. The investments, which are entered at "cost" in the balance-sheet, remain unaltered since the last general meeting, and stand at a total of £234,152. 13s. 7d. Gentlemen, these are the hard facts connected with the working of the system during the last six months, and it now devolves upon me to submit a resolution approving of the accounts. Before doing so, however, I will make a few remarks, as usual. I may say that I have probably never stood before a meeting of this Company when America was occupying such a peculiar position as it does at the present moment. The unsatisfactory state of the financial system in America, I daresay you are aware, is more or less due to the silver question. There are, however, other questions which have had more or less a part in producing the apparent collapse of confidence which we witness for the moment; but we have seen—although not so bad as at the present—very great depression from time to time. We have, however, also seen that a cycle of bad times has generally been followed by a cycle of good times, and I have no doubt that that will be the case on this occasion. There is great energy in America, which also possesses immense resources, and I have no doubt that these will come to the front as soon as the lowest depth at which the present depression is going is reached. Since I had the pleasure of addressing you last I have paid a visit to our important station at Ballinskelligs, where we have been making some rather considerable alterations and improvements, and, I may say, additions. As you are aware, when this Company was first formed, our establishment there was more or less composed of wooden dwellings, which we have to a considerable extent replaced by good strong concrete buildings. You can well understand that after 18 or 20 years wooden houses are not very much to be relied upon, and they are barely strong enough to stand the force of the wind, and certainly they would not bear any exceptionally severe strain. I was very pleased during my visit to see that everything there looked cheery, prosperous, and upon the whole satisfactory, and I came to the conclusion that as soon as we got rid of the old wooden houses, and replaced them with concrete buildings, making the position more secure, our property would be made more valuable, and the position of our people who conduct the work at that important station would be rendered more comfortable. The past half-year has been a favourable one so far as repairs are concerned. As you are aware, when our cables break a great deal of money is almost invariably expended in effecting the repairs. During the past half-year we have been exempt from that. While we have not been able to increase our dividend, we have been able, to some extent, to add to our reserve fund, which is to enable us, in the event of accidents and interruptions in our cables, to repair them. I need not, on this occasion, go more closely into the details of the working of our business. I find that the last time I had the pleasure of addressing you I went very fully into the whole position and gave you a large amount of information, as I daresay many of you who were present will remember. All I need say now is this—that we are not in a worse position to-day than we were in the last time we met. I think that, having stood the effects of the great depression that has been existing in trade generally, and seeing that we have not only maintained our position but rather improved it, we are probably in a better position to-day than we were in when I last had the pleasure of addressing you. I hope that when I see you again six months hence I shall be able to speak to you more cheerfully than I have done to-day; we are, however, passing through this trouble; but when you look abroad, and see how other people are suffering, I think you will admit that we have very little to complain of, and with a return of better trade in America, we shall naturally participate in the increased prosperity which will result. I now beg to propose the following resolution:—

"That the report of the Directors dated July 14, 1893, together with the statement of accounts to June 30, 1893, annexed thereto, be and the same are hereby received and adopted, and that a final dividend be now declared of 3s. 6d. per share, free of income-tax, making, with the interim dividends already paid, a total dividend of 3½ per cent. for the year ended June 30, 1893."

Mr. E. M. UNDERDOWN, Q.C.: I beg to second that.

The CHAIRMAN: If any gentleman has any question to put to me I shall be glad to answer it to the best of my ability.

Mr. W. GOODSALL: You have not made any statement as to the working condition of the cables. I presume that they are working well?

The CHAIRMAN: If there had been any hitch or anything of that kind you may depend upon it that I should have mentioned it to the meeting. I, however, just made the remark that during the last 6 months we have been free from any faults, and consequently we are in a satisfactory position.

The motion was carried unanimously.

Digitized by Google

The CHAIRMAN: The next resolution is

"That Charles Meara, Esq., be and he is hereby re-elected a Director of this Company."

Admiral of the Fleet the Hon. Sir HENRY KEPPEL, G.C.B., D.C.L., seconded the motion.

The CHAIRMAN remarked that Mr. Meara was not present. He resided in Antwerp, which was rather an important source of their revenue. Their colleague, however, visited them occasionally, and his absence on the present occasion was attributable to the fact that he was not quite well.

The resolution was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. JAMES PENDER, the following resolution was afterwards passed unanimously:—

That E. M. Underdown, Esq., Q.C., be, and he is hereby re-elected a Director of this Company."

The Rev. J. HUGILL then proposed the re-election of the auditors, Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A.

The motion was seconded by Mr. A. DYET.

The CHAIRMAN: I will only say with respect to our auditors that they are appointed every year. They are chartered accountants, who take special charge of our accounts, bringing them before you according to the form which they consider desirable. They are not dictated to or even advised in any way. They make out this statement, and we accept it, as a matter of course. They represent the body of the shareholders, and as far as my observation goes, I believe they represent them very efficiently. He then put the motion, which he declared carried unanimously, adding that that concluded the business of the meeting.

Mr. JOHN NEWTON then proposed a vote of thanks to the Chairman and the Directors for their services in the past half-year. It was not an easy task to steer clear where there was so much competition, and he thought that the Directors had succeeded very well.

A SHAREHOLDER seconded the motion, which was unanimously agreed to.

The CHAIRMAN: On behalf of my colleagues and myself I beg to thank you. I can only assure you that the more we feel that we have the confidence of the shareholders, the more we are satisfied to go on with our work. A little encouragement even to old as well as to young makes life go on more smoothly and pleasantly. I should be extremely sorry if it ever came to the position that our interests were not mutual. They are, however, entirely and completely mutual. The more we can make things go pleasantly and better for you, the more satisfactory is it to us. I thank you, gentlemen, on behalf of my colleagues and myself.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held at Winchester House, Old Broad-street, on the 28th ult., the Most Hon. the Marquis of Tweeddale, the Chairman, presiding.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting, and the minutes of the previous meeting, which were confirmed and signed.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, I now invite your approval of the report and accounts which have been in your hands for some days. You will observe that the receipts amounted to £146,885, being an increase of £367 over those of the corresponding period of 1892. The actual increase is somewhat larger for this reason, that in the half-year 1892, there was included an item of something like £1,600, which was really a balance which remained unadjusted for some years. Therefore, the actual difference is something like £2,000 in favour of this half year, as compared with the corresponding one. It is remarkable how little the accounts for the last four half-years have altered. In 1890 the receipts were £144,915; in 1891, I am talking of the half-year to the end of June, they amounted to £136,483, a substantial falling off, due to the interruption of communication with the west coast of South America; in 1892 the receipts reached the figures £145,000, and this half-year, as I have mentioned, they amounted to £146,885. This half-year, in reality, is the best that we have had for some time. I hope that the increase which we have enjoyed for the last six months will be not only maintained but improved. The traffic at the beginning of this month was very unsatisfactory, but during the latter part of it the returns have placed our income a little above what it was at the corresponding period of last year. The working expenses show an increase of £818, mainly due, firstly, to the loss caused by fire at St. Johns, mentioned at the last meeting, amounting to £343, and secondly to the increase of the salaries of our staff. This revision of the salaries of the staff had been promised for some years, and the matter has been taken in hand during the last six months. The average increase amounts to only £12. 15s. to each official, and the highest increment granted was £50. I do not think that any shareholder will grudge these increases. They are well deserved by long and faithful services. You will have, I daresay, observed that your Directors have agreed to subscribe £100 to the Victoria Fund. The navy has always shown a friendly disposition to the repairing ships of the various submarine cable companies throughout the world, and we thought that it was a good opportunity to show our gratitude for the assistance which various vessels of the fleet have been able from time to time to give us. The net result is that we are able to pay a dividend of 12s. 6d. per share on the Ordinary stock—not a very large one, I admit, but at the same time it is a dividend paid on stock which was very heavily "watered"—that is to the extent of 50 per cent. The proprietors have, no doubt, noticed with considerable satisfaction that the reserve fund stands at £1,007,261, or £7,000 over and above the amount which it was contemplated we should bring it up to. Whether this sum, or any other addition to it, during the current year may be made available for dividend must depend on our immunity from further interruptions and upon the speed with which the present interruptions are repaired. I am sure that you have seen with as much disappointment as your Directors that no less than two of our cables have broken down. The Brest—St. Pierre has always been a disappointing cable, and I have been looking at the number of times that it has been interrupted since we became possessed of it in 1873, as well as what it has cost us. I find that it was interrupted two or three years after we came into possession of it, and I think I am right in saying that it has been broken fourteen times since then. This has cost us something like £240,000. This is a very serious matter, and almost justifies the remark made by one of the shareholders at the last meeting, at which I had the honour to preside, doubting the propriety of repairing it any more. I do not think that we have come to that point yet, but still it is very annoying to find we have to undergo such an expenditure—something like £12,000 a year on the average, I may say—for a cable which does not yield a very large profit, which makes it all the more unsatisfactory. I may add that our ship "Minia" will proceed in a very few days to repair the two remaining faults. She has already repaired one during the half-year to which I am referring, and I can only hope that the other will speedily be accomplished. The record of the 1874 cable is a far better one. It appears to have been interrupted on two occasions, besides the present, and put us to no great expense in repairing it. The present interruption is the more serious because it is in deep water, and a great many miles from the other side of the Atlantic. The ship "Calabria," belonging to the Telegraph Construction and Maintenance Company, has been chartered for its repair. Even if these cables are repaired with the utmost possible speed and at the lowest possible expenditure of cable, the cost will be considerable. If any lengthened time is necessary and if a great many miles of cable are required to effect the repairs, I am afraid that I can hold out little or no hope of any portion of the reserve fund being made applicable to dividend. With regard to the old story of the law suit in France, I have very little to add to what appears in the report. I remember telling you at the last meeting that the delay in its settlement was very great, owing to the fact that our counsel was employed in the Panama case. Now the delay is owing to the French directorate of the Paris Company. A new Board, however, was elected a short time ago, and after the vacation we have every reason to hope and believe that the case will be proceeded with. The business of the Company has been conducted as usual with the same celerity, and I am glad to say with even increased accuracy, which is entirely due to the exertions and zeal of our *employés*, who deserve the greatest credit for the manner in which the business of the Company is conducted. I cannot conclude the few remarks I have to make without referring to the sad event which is mentioned in the report, namely, the death of Sir James Anderson. I do not propose to dwell on the valuable services, or I should say the invaluable services which he rendered to submarine telegraphy in its earliest days. These are familiar to you I have no doubt, and are indeed matters of history. Sir James was one of our Directors for twenty years. He was a man of excellent judgment, he had a very intimate acquaintance with everything connected with telegraph matters, he was most attentive to the business of the Company, and I know of no Director who had more implicitly the trust of the shareholders. I am sure you will all agree with me in a sincere expression of regret at his decease. I have also to add that our Managing Director, whose face you are all familiar with, has been for some time suffering from illness. The Board has this day granted to him three months' leave, and I hope that, at the end of that time, he will come back thoroughly restored in health. In the meantime his duties will be performed by our traffic manager, Mr. Carson, who has been in the Company's service for something like twenty years, having risen from the ranks, and he is most competent to carry on the duties of Mr. Weaver in that gentleman's absence. Gentlemen, I do not think that I have anything to add to these remarks, but I shall be glad to answer any questions that may be addressed to me. I now move—

"That the report of the Directors and the accompanying statement of accounts to June 30, 1893, submitted to this meeting be and the same are hereby received and adopted."

Mr. FRANCIS A. BEVAN seconded the motion.

Mr. BOURNE suggested that it was not advisable that any more repairs should be made to the Brest—St. Pierre cable, and further remarked that while the Chairman put its yearly cost down at £12,000, he found as a matter of fact that it averaged £30,000.

The CHAIRMAN said that it had cost about £240,000 during the last 20 years.

Mr. GOODSALL asked what was the depth of the 1874 cable.

Mr. NEWTON thought that if they had spent so much money in the repairs of that cable, surely it was reasonable to suppose that it was now becoming a good one. If they had had continuous repairs made to it, the breaks surely did not occur on the repaired parts. He thought that the matter ought to be left to the discretion of the Board. He joined in the expression of regret of the Chairman at the loss the Company had sustained by the death of Sir James Anderson, who, he said, was associated with the foundation of the Company, the work of which was one of the greatest achievements of history.

The CHAIRMAN, in reply to Mr. Daniel, said that by abandoning the Brest cable the Company would lose both in *prestige* and money, and believed, with Mr. Newton, that the last repair would add to its value. With regard to the French law-suit they must, he was afraid, take a very one-sided opinion, namely, that they ought to gain a great deal by it; but whether they would do so or not was a very different matter. They considered that they had been very badly used, and that they should

Digitized by Google

receive substantial damages; but whether that would be so or not would be determined by the French courts. In reply to Mr. Goodsall, he might say that the depth at which the cable was laid was 2,000 fathoms. They had had a good deal of trouble in connection with their cables with the owners of property on the other side, but these difficulties had been disposed of, and those that remained unsettled would be overcome within a short period at no great cost to the Company.

Mr. BOURNE having proposed a hearty vote of thanks to the Chairman which the latter duly acknowledged, the proceedings ended.

Chili Telephone Company (Limited).

An ordinary general meeting of this Company was held at Winchester House, E.C., on Wednesday last, Colonel R. Raynsford Jackson in the chair.

The SECRETARY (Mr. Edmund Petley) read the notice calling the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN: Gentlemen, instead of dwelling particularly as it has been my custom hitherto to do upon the report of the year, I shall endeavour to place before you a retrospect of the operations of the Company since we took it over from the West Coast Telephone Company of Chili on May 1, 1889. We had at that time 2,070 subscribers; the gross revenue for the 11 months up to that date was $229,000, and the net revenue $90,000. The rate of exchange at the end of the year, which was the basis of the valuation of the liquid assets in Chili, was 24d., and the net profit of the Company was £5,520. Last year we had 4,219 subscribers, and the gross revenue was $449,000, and the net revenue in round figures was $185,000. You will see, therefore, that during that period the number of subscribers and the amount of net revenue have more than doubled, and yet the profit in London last year was only £5,359. I shall place before you the reason why such a large revenue in dollars has earned so small a revenue in sterling. The average rate of exchange last year, which was the basis of the valuation per dollar of the net profits, was 18d., as against 25¼d., per dollar. The rate of the exchange at which the liquid assets in Chili were valued was 15 as against 24d. Probably the case will be made clearer to you if I deal with the results. In 1890-1, the second and most prosperous year in our history the number of subscribers was 4,028; the gross revenue was $387,000 and the net revenue was $192,000. The proportion of the expenses to the gross revenue was 58½ per cent. I ask you to bear that figure in mind as I shall recur to it later. The profits in London for the year were £13,686, and the depreciation in the value of the liquid assets owing to the rate of exchange being "18d.," against 24d. in the previous year, led to a reduction of £3,089 in the profits. I shall not dwell on the working of the year 1891-92, which was the year of the civil war, but the net profits during that period were only $107,000 against $185,000 for the twelve months, 1892-93, yet the profits in London for the former year were in excess of those of the last year. That was due to the fact that the average rate of exchange in 1891-92 was 19½d., against 18d. last year, and the rate at which the liquid assets were taken was 19d., as against 15d. in the year under review. Now there is this remarkable fact to be noted, that, although the profit of dollars in Chili was only $7,000 less in 1892-93 than in 1890-91, when the profits in London were £13,689, the net profits in London in 1892-93 were only £5,395. I have entered into a calculation with the view of ascertaining what we should have been able to put before you this year if the rate of exchange had remained as it was in 1890-91. There would have been an increase in our net revenue of £4,617, and an increase in the value of the liquid assets of £3,025. These two figures, together with the profits actually shown in the accounts, would have been equal to £13,036, so that the fall in the rate of exchange is directly responsible for a diminution in the revenue for the year of £7,642, which will enable you to judge of the cause of the difficulties which we have had to contend with. The gross revenue for 1893 was over $60,000 more than it was in 1890-91, and the proportion of the gross earnings absorbed in working expenses was 59 as against 50½ per cent. in 1890-91. The rate of exchange has affected that expenditure also. The decline in the value of the paper dollar has increased the cost of everything sold and used in Chili, and the greater proportion of the gross revenue absorbed in working expenditure is due very largely to that. If, however, the proportion of the gross revenue absorbed by expenditure had been only 50½ instead of 59 per cent., it would have increased the profits of the Company by £3,780. In short, to the fall in exchange is attributable the unsatisfactory statement of the accounts which we have been obliged to place before you. It may be asked what, under the circumstances, do the Directors propose to do? The fall in the rate of exchange is not solely due to the fact that silver money prevails in Chili, and that we have a gold standard here, but it is attributable to the circumstance that there is a forced issue of paper money; and whereas you can estimate pretty nearly what the value of the silver dollar will be when you know the price of silver, there is no possibility of measuring the value of the paper dollar, the issue of which is not limited. The Chilians themselves have shown us how to deal with this matter. The Government itself has put up the tariff of its railways by 25 per cent., the gas companies have put up their charge by 50 per cent. Labour of all kinds is advanced by about 50 per cent. Rents have advanced 50 per cent. Therefore everybody having anything to sell or trade in in any way in Chili seeks to protect himself from the depreciation in the value of the paper money by securing as much as he can of that money, and your Directors have come to the conclusion that they must follow the example of the Chilians in that line of policy. We have put up the rates in some important centres in Chili, and are about to do the same in all of them; and we think that our position will be improved to a certain extent from that cause alone. I think that we have another source of hope. The President of Chili has announced the determination of the Government to do away as soon as possible with the forced issue of paper money. He has not simply announced that that is the intention of the Government, because on September 26th last year an Act of Congress was passed with the view of accomplishing that object. It was found not to be altogether the best Act that could be passed for the purpose, and it was modified, I believe, in March this year. But the President has not only declared that the forced currency will be stopped as quickly as possible, but he has indicated the source from which he hopes to derive the means of accomplishing the object of the Government. The Government is not approaching the subject in a light spirit. It seems to be dealing with it with forethought and resolution; and knowing, as we do, the determined and courageous character of the people who are in this matter supporting the Government, we may feel quite certain that they will give effect to that which they regard as being essential to the well-being of the country. The President has pointed out that after the fourteen years' experience which they have had, a forced currency and excessive fluctuations in the exchanges and the value of the paper money, are adverse to the trading interests and commerce of Chili, and that, therefore, it is necessary in the interests of the whole people that effect should be given to a sound financial policy. We have, therefore, reason to hope that with the advance in tariff which we feel it our bounden duty to the shareholders to make, and the sound financial policy foreshadowed by the Government, we may find that our enterprise will end in being eminently successful, and will justify the hopes originally held by the shareholders with regard to it. We feel that there may be some delay because the President has declared that it will take till 1896 to give complete effect to the policy of the Government, but it will be gradually working towards that end. But there is another ground upon which your Directors rely for thinking that it is possible in the current year that they may be able to set aside out of revenue sufficient to enable them to pay a dividend at the end of the year. We have practically closed, for the present at least, our capital account, and we are only spending money which is necessary to take up new subscribers, and, therefore, most of what we earn in Chili will be available for fulfilling the postponed hopes of our shareholders. I do not know that I can say anything more to elucidate the position of the Company. I do not like under circumstances such as these to indulge in prophecy. You will understand that what I have mentioned to-day is merely the belief of the Directors, and that there is a reasonable prospect of what I have indicated being realised. I beg to move:—

"That the report of the Directors with the statement of accounts now presented to this meeting be approved and adopted."

Mr. THOMAS GREENWOOD seconded the motion.

Mr. J. R. BAILLIE asked whether the rate of exchange was not now 14d.?

The CHAIRMAN said that it was 14¾d., but that it had been as low as 14d. The average rate for the year to which the accounts related was 18d. If they had been able to value their net revenue this year at 2s., as was the case in 1891, that alone would have increased their profits by £4,617, and if they had been able to value their liquid assets at the same rate, which was 18d. instead of 15d., they would have increased the profits by £3,225: and instead of showing £5,394 as the result of the year's working, they would have shown £13,036, so that the fall in the rate of exchange since 1890 had adversely affected the Company to the extent of £7,642. The Directors were not able to announce what the increase in the subscriptions would be, but they calculated that it would have a material effect on the receipts during the year.

Mr. BAILLIE further remarked that from what he saw of the property in Chili and its management, he ventured to say that their undertaking was in a very good condition indeed, as compared with other commercial enterprises there.

The CHAIRMAN said that he was glad to hear Mr. Baillie give expression to that belief, and in this connection he might point out that the results in Chili were very satisfactory, as there had been an increase in the gross earnings.

Dr. JOHNSON asked whether it was likely that there would be any opposition on the part of the Government or the municipal authorities to the Company raising its tariffs.

The CHAIRMAN replied that it was not likely that such opposition would come from the Government, with which they had very large contracts. At any rate, they did not now apprehend it.

The resolution was then carried unanimously.

The CHAIRMAN next proposed:

"That Mr. Thomas Greenwood be, and he is hereby, re-elected a Director of the Company."

He paid a warm tribute to Mr. Greenwood for his services to the Company.

Mr. E. QUILTER seconded the motion, which was agreed to *nem. con.*

Mr. GREENWOOD having expressed his acknowledgement,

The CHAIRMAN moved:—

"That the Hon. F. Ernest Allsopp be, and he is hereby, re-elected a Director of the Company,"

remarking that that gentleman's practical suggestions were often of great value to the Board.

Mr. COLE seconded the motion, which was carried unanimously.

Mr. BAILLIE proposed, and Mr. QUILTER seconded:—

"That Mr. Thomas A. Welton be, and he is hereby, re-elected auditor of the Company."

On the motion of Mr. COLE, seconded by Mr. BAILLIE, a cordial vote of thanks was accorded to the Chairman, Directors, and staff of the Company for their services during the year.

The CHAIRMAN, in returning thanks, observed that it was not when the profits were largest, and the general results of an undertaking were

Digitized by Google

most satisfactory, that the Directors had the hardest work to perform; but he hoped that the time would soon come when the shareholders would pass such a vote even more cheerfully and with a feeling of greater satisfaction at the result of the working of the Company. The proceedings then ended.

City and South London Railway Company.

The eighteenth ordinary general meeting of this Company was held on Tuesday at Winchester House, Old Broad-street, under the presidency of Mr. Charles Grey Mott.

The SECRETARY (Mr. W. F. Knight) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: It now becomes my duty to move the adoption of the report and accounts. You will be pleased to see that the steady increase of receipts has continued during the past half-year, in spite of the long-continued fine weather, which you know, on most occasions, is detrimental to the traffic of this line. On the other hand, we have the satisfaction of stating that there has been no increase, but, on the contrary, a small decrease in the expenditure, so that we have an increased receipt with a decreased expenditure—always a satisfactory condition of things in all companies. Then, we have again to report that the line has been worked with the greatest regularity, and without any stoppage or interruption. The line itself, I think, is growing in popularity. The public find that it has an almost unexampled regularity of service and perfect punctuality; that it has a pure atmosphere, free from all noxious vapours; that it has an even temperature, which is pleasant both in summer and winter; and that, altogether, the line is one such as was wanted very much in the metropolis; while it is a great improvement upon all existing communications. I will now shortly call your attention to a few of the items in the accounts. In the first place, as regards the capital expenditure we have raised £17,050 during the half-year, which we have used in paying off liabilities amounting to £10,209, and in expenditure upon the Stockwell sidings and various other matters amounting to £6,181. Those items account for nearly the whole of the capital expenditure. We have paid off during the half-year £3,800 of the terminable debentures, and have replaced them by Four per Cent. Debenture Stock issued at a premium, so that we have effected a small saving there. The amount of debentures which fell due this half-year was exceeding small, but in the future we have a large amount maturing, and we shall have an increased saving each half-year until we get the whole of these paid off and converted. We now come to the most interesting account, the revenue account. The receipts from passengers have increased £1,491 in the half-year, and from season tickets there has been an increase of £36. Parcels receipts are £9 more, transfer fees show an increase of £4, from rents we have derived an additional £78, and sundry receipts have given us £21 more. You therefore see that there has been an increase in every department of receipts, making the total improvement for the half-year £1,639. On the other hand the expenses for maintenance have increased £13, but locomotive expenses have decreased £159; carriage repairs, as might be expected, have increased by £57, but traffic expenses have decreased £124. The general charges are £160 higher. I may state that the increase in general charges is largely due to what I think you will approve—that is, the insurance against accidents. We have thought that on a small line like this, although the liability to accidents is exceedingly small, yet still, in the early stages of the railway, it was not desirable to run any risk which might interfere with our dividend. We have, therefore, entered on an insurance against accidents, and by paying £200 a year this will insure us up to a limited amount, though a considerable amount, both annually and for each accident. I hope that the accident company may reap the benefit, and that we may have no claim on them, but I think you will agree with the Board that it was a prudent course to adopt. It is that, however, which has caused the increase in our general charges. We have had to pay this half-year £24 for passenger duty, which has not appeared in previous half-years. I daresay some of you have noticed that questions were asked in the House of Commons on this subject. The fact is that this matter has been under discussion for some time with the Inland Revenue Department. We issue no tickets, and we give every passenger the right to travel the whole length of the line. Our contention, therefore, was that we had no means of knowing how far a passenger travelled, and if he had the right to travel the whole length of line, he was not liable to duty, as it came to less than 1d. a mile. The Inland Revenue contended that a certain number—not a large number—did not travel a sufficient length to make the rate 1d. a mile. It was impossible on the part of either the department or ourselves to ascertain the number, and we eventually agreed on a compromised arrangement. The passenger duty is thus chargeable with £24 for what was due for the past half-year and one or two previous half years under that arrangement. The law charges have decreased £52, rates and taxes have increased £44, and compensations have decreased £117. The consequence is that there is a net decrease in expenditure of £134, which, added to the increase in the revenue, makes the net improvement £1,773. With regard to the increase in rates and taxes, that has been going on steadily, and I am afraid that we must look forward to a still further increase in the future. It has affected all railways in the country as well as individual householders. Unfortunately, there is a spirit abroad in this country of a retrograde nature, which is going back to the exploded theory of Cæsarism, by which everything is to be done for the people and nothing by them themselves. It has always been found in the past—and, no doubt, it will be found in the future—that that doctrine led invariably to a large increase of public expenditure, and at the same time took away that self-help and self-dependence which is the great strength of all nations. As long as that spirit is abroad you will see steadily year by year an increase of all rates and taxes, both Imperial and local; and until we have found out the mistake of our ways, I am afraid that we must look for a steady increase in that direction. You will be interested to hear the percentage of working expenses on this line—what it has been in the past, and what it is at present. In the first half-year the expenses were 79 per cent., in the second half 76 per cent., in the third half 70 per cent., in the fourth half 67·9 per cent., and in our fifth and last half 64·6 per cent. You therefore see that there has been a steady, regular decrease in the percentage of expenses to receipts. I hope that that will go on in the future as in the past, until we get the expenses down to a much lower rate than they stand at present. As I have pointed out before, these expenses include the item of the lifts, which is not an expense connected with other railway companies, who have no lifts. If you deduct the cost of working these lifts, our expenses, as compared with those of other railway companies, would be only about 56½ per cent. of the receipts, which is very nearly the same as those of many of the ordinary larger railway companies. It may be interesting to notice the changes which have taken place in the receipts per train mile on this line. We began our first half with a receipt of 2s. 1d. per train mile, in the second half it was 2s. 1½d., and in the third half it was 2s. 2½d. We then put on a large increase of mileage, the effect of which was felt by the receipts being reduced by 2d. per train mile. We have only put on this half-year a small additional mileage, and the result is we are overtaking the large addition of train mileage previously put on, and the receipts per train mile have risen to 2s. 1½d. The expenses per train mile, on the other hand, in our first half-year, were 1s. 9½d., in the second half-year 1s. 7¾d., in the third half-year 1s. 7¼d., in the fourth half-year they were 1s. 5¼d., and last half-year they were 1s. 4½d., which is going down at a very satisfactory ratio. Our locomotive expenses in our first half-year were 9d. per train mile, in the second half-year they were 7·9d., in the third half-year they were 7·7d., in the fourth half-year they were 7·1d., and this last half year they have been 6·48d. As I have pointed out to you on various occasions before, if you compare that rate of working of locomotive expenses with those of the large railways of England—such as the North-Western the Midland, the Great Western, and others—you must take off the carriage of the coal which we pay for and they do not. Deducting that, the locomotive expenses would be reduced to 5¼d. in the past half-year, which is very little more than half the rate which the large railway companies of England now pay for steam purposes. The receipts for each passenger in the first half-year were 1·90d., in the second half-year 1·70d., in the third half-year 1·73d., in the fourth half-year 1·60d., and last half-year 1·66d. These figures have varied mostly in consequence of the increase or decrease of the local short-passenger traffic. A year ago we tried in various ways to get a mid-day traffic, and a number of short distance passengers at low fares, and we were successful in that, but the result was that although we got a general increase in receipts, it diminished the receipt per passenger from 1·70d. to 1·60d. This half-year, however, we have a general increase in long-distance traffic, and the receipt per passenger has risen to 1·66d., or very nearly the figure it was before we made the reduction. The new sidings at Stockwell, referred to in paragrah 7 of the report, are practically completed, and will very shortly be brought into use. We are anxious to have them in use before the winter traffic commences, and they will be ready before that time arrives. I think they will enable us to give a somewhat improved service this winter. We have also, by putting on an additional signal between Stockwell and the Oval, been able to improve the service somewhat in the past half-year. Our Bill for the extension to Islington has passed the House of Lords. It has been read a third time, but has to go the House of Commons to obtain its consent to some alterations, and then it will remain for the Royal assent. In order to try and improve the King William-street station at the surface we have acquired the lease of the adjoining premises in Arthur-street East. The station at the surface is dark and confined at present, and it is very difficult, owing to the small space available, to make any improvement, but we have been very anxious to do so, and having the opportunity of acquiring the lease of the premises mentioned at a moderate price, we have availed ourselves of it, and are now considering what alterations we can make, at a small expense, by which we may somewhat improve the access at the top of King William-street station. I do not know that there is anything more that I need detain you with, and I beg to move that the report and accounts now presented to the meeting be received and adopted.

Mr. CHARLES SEYMOUR GRENFELL briefly expressed his pleasure in seconding the motion.

The resolution was at once carried unanimously, without discussion.

The CHAIRMAN then proposed a dividend at the rate of 5 per cent. per annum on the Preference shares for the half-year ended June 30th last.

Mr. SAMPSON HANBURY seconded the motion, which was carried unanimously.

The CHAIRMAN afterwards proposed the payment of a dividend at the rate of ¾ per cent. per annum on the Consolidated Ordinary Stock for the half-year ended June 30th last.

Mr. S. BARCLAY HEWARD seconded the motion, which was unanimously adopted.

The CHAIRMAN: That concludes the business, and I hope that each time we meet we may have an improved dividend to declare.

Mr. DRAKE then proposed a vote of thanks to the Chairman and Directors. The shareholders recognised that amid many difficulties—theirs being the pioneer electric railway of London, and therefore having to gain experience for all similar undertakings in the future—the undertaking was progressing, and they might congratulate themselves on the improved dividend and on having carried such an enormous number of passengers without injury to life or limb. The service had been extremely regularly and punctually performed with very few hitches in the half-year, and this was a fact which, in addition to the financial aspect, should give great pleasure to shareholders as well as to Directors. It would be well if the lighting of the carriages could be somewhat improved.

Mr. JOWETT seconded the motion,

Digitized by Google

The motion was carried unanimously.

The CHAIRMAN: I beg to thank you very heartily for the kind way in which you have passed this vote. I can assure you that votes of this kind are the greatest encouragement to Directors in continuing to do their very best for the shareholders. When they feel that their efforts in the past have been appreciated, it makes them double them in the future; and I am sure that all matters connected with this railway will have our very best attention. It is a labour of love with some of us, and they intend to make the line a success—and a great success—before they have done with it. The lighting of the carriages is a matter that has engaged our attention perhaps more than anything else. It is an important question, but it is one of the most difficult we have to deal with There are difficulties which beset us on every side with respect to the lighting, but we are determined to overcome them, and we are busy now in making certain tests with this object. I look forward with confidence and hope to the future of this undertaking. Its progress may be slow, but it will be absolutely sure, to my mind; and if we go on in the future as we have done in the past, I feel sure that the day will arrive when none of you will be disappointed with the dividend.

The proceedings then terminated.

Edison and Swan United Electric Light Company (Limited).

The annual meeting of this Company was held on Friday, at the Cannon-street Hotel, Mr. J. Staats Forbes (Chairman) presiding.

The SECRETARY (Mr. H. Charles Gover) having read the notice convening the meeting,

The CHAIRMAN said: I think the essential part of the report is in a nutshell. And it is embraced in this—that the gross receipts of the year are the largest the Company have ever obtained, and that the expenses are exactly of the same description, for reasons which I will explain more fully presently, while the net profits of the year have increased by £11,831. The position of the Company is, as you know, now approaching a moment when there will be a considerable change. The period of protection will expire in November, and we should have been very much wanting in our duty to you if we had not anticipated that event for some years. We have been working on a well-considered design for a number of years, the design being that when we emerge from protection we shall be prepared for competition, of which I daresay we shall have some. This is the tenth complete year of our existence. and it is rather curious, and worth while calling your attention to the fact that, during the first five years, we paid no dividend at all, and we began the sixth year with an enormous incubus in the shape of a cumulative claim by the "A" shareholders of £121,000 in round numbers. During the past five years, the business having prospered, and the electric light having extended somewhat rapidly in comparison with the earlier years, we have been enabled not only to pay the 7 per cent. preferential dividend secured to the "A" shareholders, but to wipe out that large sum of £121,000. Therefore we emerge from the protected period having paid the preferential 7 per cent. for the whole of the ten years, while for this present year we propose to pay an additional 3 per cent.—making 10 per cent. If you will turn to the profit and loss account, you will see there is a credit balance of £86,642, and if you look at the statement showing the proposed appropriation of the profit you will see how we recommend the disposal of that amount. When we commenced the year the balance of arrears of the cumulative preferential dividend on the "A" capital was £8,261. That was the remainder of the £121,000 which we began with five years ago. That £8,261 had to be got out of the way, and we did it by means of an interim payment at the end of the first six months, in addition to which we paid 3½ per cent. for the half-year ended December 31st last, amounting to £12,371, on the "A" shares. Well, we now propose to make up the 7 per cent. preferential dividend for the year, which the holders of those shares are entitled to, and for the first time in the history of the Company the position of the Deferred, or "B," shareholders has to be taken into account. This £117,000 worth of shares represent the interest of Mr. Edison and his friends, and is the purchase price of the patents and the formation expenses of the Edison Company, and they are held subject to the condition that they participate to the extent of one-quarter in any profit of the undertaking after meeting the seven per cent. preference claim of the "A" shareholders. As you will see there is a considerable surplus after the payment of that seven per cent., and we have proposed to pay three per cent. over and above the seven per cent. distribution upon the "A" shares, and, of course, the same amount upon the "B" shares, which, for the first time, participate in the profits. I hope it will endure. We also carry over the very considerable sum of £39,498. Seeing what is before us, and the necessity of a pretty strong reserve, the Directors have deemed it prudent to err on the right side, and they think that having paid off all the accumulations on the "A" shares it would be wise to have a large reserve. The Board, therefore, have no hesitation in recommending a ten per cent. dividend instead of a larger one, which would be possible if we trenched further upon the profit of the year. What we have to consider, of course, is whether the profit of the year, as shown in the figures I have given, is likely to be maintained in the face of the competition which may be tolerably severe. Well, we have laid our plans so as to be prepared to face it. We shall not escape the inevitable, but we must endeavour to hold our own, and we think that with the good organisation, the large connection, the strong reserve, and the good name we possess, we may be able, if not to attain such large results as during the protected time, at all events to retain sufficient business to make our dividend a very fair and reasonable one. What it will be no man can tell, and I am not going to prophesy. We shall have to keep our eyes open and put our best foot forward during the next two or three years. With that view we have become manufacturers as well as lamp makers. For a very long time we were so bitten in the earlier years by the errors of the two Companies—the Edison and the Swan—in entering upon installation business and contracting for supplying light and so forth, the effect of which was so nearly disastrous that we determined not to touch that kind of business at all until we saw our way very clearly. Consequently, for a number of years we pursued the humble role of lamp makers. Latterly we have emerged into the business of manufacturers connected not with the lamp as a lamp, but with the appliances for its fitting and installation in houses and elsewhere. And although the lamps patents expire in November we have valuable patents in connection with the appliances which are already bringing in a considerable annual revenue, and which extend for a tolerably long term of years. In respect of these patents for holders and so forth we have commenced to manufacture for ourselves, charging ourselves the same royalty as we charge our licensees, and we have a great number of leading firms in the lamp fitting business, the gas fitting business, and the brass founding business who are competing with us in the sense that they are bound to sell at the same price as we do and to pay us a royalty on our manufacture. We found that the nature of the business required that that course should be followed. As I have said already, in the present development of lamps there is a considerable annual royalty coming in from that, which I have no doubt will grow rapidly from year to year, because it may be prognosticated with, I think, some degree of reasonableness, that electric lighting is now pushing ahead pretty fast and that the cheaper the lamp the more will electric light be used. While the lamp is sold at one price, under protection, people are probably more careful than if it was sold at some more moderate price in the open market. It will suit our purpose to have a considerable multiplication in the sale of lamps even if the price is lower than that which has ruled during the protected period. We must look to multiplication. The fixed charges of manufacturing are considerable and are not influenced by the number of lamps sold. You may double the number sold without increasing some of those items which form a tolerably fair percentage of the cost of carrying on business, and we have now obtained a position in which we can produce lamps as cheap as anyone in this country, or probably in Europe. Then the reputation of our lamps may be said to have been established. We can, of course, only induct from our experience. We had Edison lamps constructed in America, and our own, the Edison and Swan, constructed on Mr. Swan's methods in England; and although our customers were free to select which lamp they preferred, the Edison lamp has almost disappeared, which, at all events, is some sort of proof that the Swan lamp was not inferior to the Edison. Of course, when competition begins we shall have lamps imported from Germany and all parts of the Continent. Well, we know pretty well what other lamps are, and I dare say we have enough knowledge to be able to measure their possibilities; and although no doubt the number of lamps we sell may be affected, we must look to the general development of the business and to our being able to hold our own in the total output of lamps, which must be from year to year greatly increased, because it is only just recently that the electric lighting business seems to have moved. One has the opportunity of reading in the papers the speeches of gentlemen connected with electric light companies, and we have a natural interest in following their remarks. We read that the Westminster Company have 120,000 lights instead of 60,000, and that the St. James's have doubled theirs, and that the Chairman of the London Electric and the Metropolitan for the half-year or year, when he comes before his proprietors, is enabled to say that the number of their lights has increased by so many thousands. All this indicates the rapid multiplication of lamps. Hitherto we have had something like a monopoly, but not an entire monopoly, because in spite of the best endeavours a certain number of foreign lamps have got into the country, but not in any serious proportion. When the time comes we must endeavour to hold our own relatively to the general advance in electric lighting, and if the result is achieved, which I believe from my connection with the Company I can foresee—that there will be a great spurt in this business, an immense extension of it during the next few years—if that result is achieved what is now a comparatively small number of lamps will become an enormously increased number. I dare say gentlemen who walk about London with observation notice now two curious things. You see a house being redecorated or undergoing repair, or being built, and on the front there meets your eye the name of the builder, so-and-so, and also a board announcing that the electric light installation is by so-and-so. That is to be seen all round the squares and streets and down the tortuous lanes, and wherever you go. This state of things gives us hope of a growing business in the future, coupled with which we look forward to a large increase in the manufacturing business, which means a great number of interesting, necessary, and somewhat costly things, such as switches, pendants, holders, switch boards, and such like things, upon which, of course, the profit per article is considerably greater than upon such a very small implement as a lamp. We have also prepared ourselves for that. We have the premises, the skill, the experience, and the money at our backs—reserve, most of it. Having said thus much I think I have communicated sufficiently our position, warning you that there is the past, like there is in a man's life, a subject of retrospect, and the indefinite, which is a mere matter of speculation. There are one or two general things I should like to call your attention to. The gross income for the year, including the stock, you will see by the accounts, is £240,271, as against £212,048 last year, an increase of £28,223. The gross expenses have been £153,629, as against £137,237, or £16,392 extra, leaving an additional profit of £11,831. I have one or two observations to make about that £16,000. It is a considerable addition no doubt, but during the past year, for the first time, we have had to bear the burden of establishing a number of depôts. When we are competing with others, and our business extends, people who live in the great centres of industry would

Digitized by Google

probably get tired of drawing their supplies from the factory at Ponder's End; and as a matter of fact, looking forward, we were determined to try the experiment of having a London depôt, and so we opened one in Parliament-street, Westminster, where we have done an extremely good business. At this depôt our lamps have been visible to passers by, with the result that customers have been attracted. We have become, in fact, traders in lamps on our own account, at the same time paying due regard to the interests of what is called the trade, because, of course, our business is to be all things, as far as we can, to all people. We do not feel it prudent to leave ourselves entirely in the hands of installers or traders. We have now an enormous *clientèle* over and above the trade, but, as a matter of course, we do make the trade certain allowances in the shape of discount, because the trade undertakes certain risks and relieves us of them. We are so satisfied of the wisdom of establishing these depôt that we have recently opened one at 110, Cannon-treet, where any of you gentlemen will be welcome to call and see what we have, and the multiplicity of articles on sale connected with the lamp business. We have altogether twelve of these depôts. Two are in London, and both are doing extremely well. Although the Cannon-street depôt has been opened only about a year, it has attracted a considerable number of customers, and I have no doubt that these different depôt are valuable adjuncts to our Company. In the provinces we have opened depôts at Birmingham, Cardiff, Liverpool, Leeds, Newcastle, Hull, Dundee, Glasgow, Belfast, and Dublin, and we are doing business in all these places, and look forward to its being increased. We have had the good fortune to be served by some admirable officers, amongst others a commercial gentleman who has charge of these different depôts, and whose business it is by means of advertising and travellers to bring our wares to the notice of the public. That sort of thing, of course, costs money, and of the £16,000 extra expenditure, £7,830 is attributable to the expenditure incurred in establishing these eleven new depôts. Of course, we hope that we are throwing a sprat to catch a mackerel. I think these depôts will be quite indispensable, because when the period of competition comes they will be one of the means of obtaining business in the great centres of industry. Another thing I have to call your attention to is our position with regard to the solid asset of the Company, by which I mean our tangible property. You know we were founded on patents, which we have had the enjoyment of for ten years, and, in a certain sense, for the preceding years of the life of both Companies, before they became one, and in which time they both made a pretty mess of their affairs. As a consequence we have had many thousands of pounds to write off these patents altogether, apart from any benefit you, as a united company, have had from them, before we were in a position to pay any dividends at all. The position is this. The "A" or Preferred capital of the Company is £353,478, which has a cumulative claim to a seven per cent. dividend before the "B" shareholders get anything, and it takes £24,743 to pay that 7 per cent. Besides the £353,478 which is subscribed capital, we have £117,820 worth of deferred capital in virtue of the benefits accruing from the patents. As these patents expire in November next there is not much value to be attached to them for the future. The holders of that £117,000 worth of capital are entitled to a quarter of anything earned after paying the 7 per cent. on the "A" shares. As I have said before, I hope they will get something, and I think there is a probability that they will. But we are more concerned with the people who found the money—the £353,000 odd. Now, of that amount we have got £200,000 in a solid asset in the nature of freehold property, plant and stock, debtors and Consols. Of course I am obliged to suggest that that asset is valued as part of a going concern. It is less than what it originally cost, because we have carefully, from year to year, written down these items, and £200,000 is much within the value of these things as long as they continue parts of a going concern. I do not mean to say that these different assets could be sold in the open market, like bread and butter, to-morrow morning and realise that amount. But the necessity of doing that is not within the bounds of immediate probability. Then it comes to this, is our position and experience, our capacity to supply any demand, and our trade mark worth the balance of our capital? You are as capable of judging that point as I am. I am sanguine enough to believe they are. I think we need be under no apprehension that our venture will cease to be certainly a reasonably profitable one, and probably a very profitable one, because with the multiplication of lamps we shall speedily retrieve the loss which may ensue upon the sale price when we emerge from our protected period. I do not know whether anyone will be curious upon the subject of the accounts. I shall be happy to enlarge on them, but I think they speak for themselves, and there are many gentlemen present competent to ask questions upon them. If anyone should desire an explanation of any particular item I shall be pleased to answer him. I think I have now said enough upon the question of the accounts and the position of the Company, and therefore I will move—

"*That the report and accounts for this year ended June 30, 1893, be received and adopted.*"

Major S. FLOOD PAGE (Deputy-Chairman) seconded the motion, which was unanimously agreed to without discussion.

The CHAIRMAN, in proposing the following resolution, which he described as one of the most complicated things he had ever had to deal with, said that the more critical shareholders would see that the amount of the dividends recommended in it was not quite in accordance with the figures in the report:—

"*That a dividend be and is hereby declared on the "A" shares of the Company of* 4s. 0½d. *per share on the* 89,261 *Ordinary shares,* £3 *paid; of* 6s. 8¾d. *per share on the* 5,000 £5 *fully-paid shares allotted to the Edison Electric Light Company (Limited); of* 5s. 0½d. *per share on the* 12,139 £5 *fully-paid shares allotted to the Swan United Electric Light Company (Limited); and of* 3s. 2d. *per share on the "B" shares of the Company; being, with the interim dividend paid on March* 14, 1893, *a payment on the "A" shares of the Company of the balance of arrears of cumulative Preferential dividend, and of* 10 *per cent. in respect of the year ended June* 30, 1893; *and on the "B" shares of the Company* 3 *per cent. in respect of the year ended June* 30, 1893. *All to be distributed in accordance with the provisions of Clause* 37 *of the Articles of Association, income-tax free.*"

Major FLOOD-PAGE seconded, and the resolution was carried.

Mr. H. R. HEDGES asked for some information with reference to the negotiations for the amalgation of the Company with the Swan Company. He also expressed the hope that if any such amalgamation took place it would have the effect of reducing the charges for administration.

The CHAIRMAN: I am glad the shareholder has asked me this question, as it affords me the opportunity of telling the meeting something about this matter. It is a subject we feel the importance of from year to year, and the importance of it becomes accentuated as the period for the expiration of our patents approaches. Our attention during the past twelve months has been given to it, and propositions have been formulated, and I suppose I may say substantially agreed to, setting forth the conditions upon which the Edison and Swan United Company are to take over the remainder of the business of the Swan Company. You are aware that the Swan Company hold 60 per cent. of the "A" capital of our Company, but that only represents what is called the British business. We retain for our own benefit what is termed the foreign business, and we succeeded in affecting a fusion with the French Edison Company, in which we hold a certain amount of capital, which has paid, during the few years we have been connected with it, a reasonable dividend. But we have never been able to succeed in Germany, where we had prolonged litigation, which prevented the use of our lamps. People there were threatened by us that if they used the Edison lamp they would be infringing our patent, and they were threatened by the Edison people that if they used the lamps made by us they would be liable to damages. That sort of thing went on a great many years, and then our patents were declared not to be an infringement of the Edison patent. After that result we made up our minds to continue our business in Germany until we could see our way to dispose of the whole thing. There are many complications which it will probably take a long time to render clear, but they all point to putting the remnant under the parent umbrella, and the terms are practically agreed to. Lord Lichfield and Sir John Lubbock, M.P., were good enough to act for the Edison and Swan United, and Mr. Quilter, M.P., and Mr. Swan acted for the Swan Company, and they have arrived at a certain conclusion which, however, cannot be carried into effect until a little internal matter has been settled. You know that we have in our Company a certain number of fully-paid shareholders and some partly-paid ones, so that when we come to sell the remainder of the business for a consideration we have to determine what a reasonable apportionment amongst the two classes of shareholders would be, and that is a rather difficult thing to do. It involves looking into the future, as the apportionment must be founded partly upon present values and partly upon an unknown quantity; that point has occupied the attention of the gentlemen to whom I have referred for a long time, but Mr. Quilter, representing, I think, more fully what I may call the partly-paid interest, and Mr. Swan representing more particularly the fully-paid interest, have come to an arrangement. At the first blush I confess I did not like the look of it, but when I heard the arguments I came to the conclusion that it was a reasonable and fair proposition, but the Directors can do nothing until the shareholders have agreed to it. We had a meeting yesterday of the fully-paid shareholders in the Swan Company to put the matter before them and we hope the arguments which satisfied them will meet with the approval of the general body when we can get them together. It will have to be submitted to an aggregate meeting, and then we shall have to submit the bargain to the shareholders of this Company. One of the objects of the proposed fusion is to effect economies in the administration, and there is every reason to believe that that result will be the outcome of it.

The retiring Directors, Major Flood Page and Mr. Bidwell, F.R.S., were then re-elected.

Messrs. Welton, Jones and Co. were also re-appointed auditors, and the meeting terminated with a vote of thanks to the Chairman.

Manchester Edison-Swan Company (Limited).

The eleventh ordinary general meeting of this Company was held on Friday, Mr. V. K. Armitage, Chairman of the Company, presiding. The annual report of the Directors, which was taken as read, stated that the net profit, including last year's balance, amounted to £2,047. 14s. 9d. Of this it was proposed to devote £1,000 to the payment of a dividend at the rate of 5 per cent. per annum, and £873. 15s. towards the loss incurred in connection with the Williamson Electrical and Engineering Company (Limited), of Australia, carrying forward a balance of £173. 19s. 9d.

The CHAIRMAN, in moving the adoption of the report, referred to the depressed state of electrical business and business in general during the past year, and said that the Manchester Edison-Swan Company had suffered a good deal through the delay of the Manchester Corporation in carrying out their installation, as people did not care to go forward with installations on their own account till they saw what the Corporation were going to do in the matter. The Corporation seemed now to be within measurable distance of the completion of their works. The net profits of the Company had been about £800 less than in the preceding year. Although the result was to that extent unfavourable, he was not without hope as to the future of the Company. There could be no doubt that there would be a very great spread of electric lighting in the immediate future, and they hoped and believed they would get their share of the work that had to be done. Nearly all the business they had done had been

Digitized by Google

remunerative work, and with increased business they would have an increase in the amount of their profits.

The motion was seconded by Mr. W. P. JAMES FAWCUS, and after some criticisms on the accounts by Mr. C. Hopkinson, it was put to the meeting and adopted.

It was agreed that the profits should be disposed of in the manner suggested in the report, except that out of the balance to be carried forward, £150 was voted as remuneration to the Directors. Votes of thanks to the Chairman and other Directors concluded the proceedings.

Crompton and Co. (Limited).

The fifth annual general meeting of the members of Crompton and Co. (Limited) was held at the City Terminus Hotel, Cannon-street, on Monday last, July 31st, Viscount Emlyn presiding.

The SECRETARY (Mr. Francis R. Reeves) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said: Gentlemen, in rising to move the adoption of the report, although we meet you with a diminished dividend, I am quite sure that I am justified in congratulating you upon the progress and position of the Company. First, as regards the business done, I am glad to say that the turnover shows a satisfactory increase over the previous year, and the gross profits on trading an increase of nearly £3,800. This progress has been made in spite of the severe commercial depression which has affected (more or less) all classes of business, and consequently checked the receipt of orders for our goods. One country alone, Australia, which through our affiliated Company has formerly been a large customer for our goods, has taken very little from us during the past year. There are, however, now signs that this trade is likely to improve, the orders booked during the past three months being nearly equal to those for the whole of the previous year. The outlook from South Africa is also promising. During the past year the cost of manufacturing goods at the Chelmsford works has again been considerably reduced, and, in fact, so far as regards economy of management, the Directors feel that they have every reason to be satisfied with the progress made in this direction. Unfortunately, the year has suffered from some exceptional and unforeseen expenses, the principal of which were those attending the temporary arrangements consequent on the breakdown of the boilers at Chelmsford Works. The water supply there, though expensive, is unsatisfactory in quality, and the boilers, when the heavy pressure of the town lighting came on last winter, gave out altogether, and before new ones could be got in to take their place temporary boilers had to be hired and put into position at great expense in order to keep the works and the town lighting plant going. Since this trouble the Directors have got new boilers into position, with water-purifying plant, and substantial savings are now being made in this department. Another item of expense beyond the normal amount has been the cost of advertising and exhibitions. This account is being closely watched, so as to effect considerable reductions during the current year. The extraordinary general meeting of the shareholders last October sanctioned the nominal increase of capital of the Company to £300,000. The cost of registering this capital, and the expense of issuing prospectuses and advertising, have been temporarily charged to a suspense account, and will be written off in equal instalments in about three years. Since the last meeting 2,781 Preference shares and 1,928 Ordinary shares have been placed. The list of applications for Debentures has also been closed, and the Committee of the Stock Exchange have granted a quotation in the Official List for these securities. This is an evidence that all formalities have been properly complied with. The stock-in-trade shows a considerable increase over the previous year, a satisfactory feature, as the increase, consisting as it does mainly of finished parts of the machines, enables the Company to make quick delivery, and this fact often secures an order. The item "Trade Debtors" shows an apparent decrease. This is due to the transfer of the Chelmsford lighting account to "Investments." With regard to the "Profit and Loss Account," for the reasons already mentioned, the net profit is some £3,000 less than last year, and the Directors do not, therefore, recommend the full dividend on the Preference shares. They feel sure, however, that the shareholders will agree with them that this is the proper course to adopt. As far as the Preference holders are affected, I may point out that their dividend is cumulative, so that the balance (1 per cent. for the year) which is unpaid now is carried forward to next year, and is a first charge after Debenture interest on the future profits of the Company. The Board have every confidence in the future. The works at Chelmsford and at Lillie-road are in first-rate order and well equipped. The Company has a good staff of engineers and officials, most of them old hands, and is served by an excellent body of workmen. It will be gratifying to the shareholders to learn that the Crompton arc lamp has been so improved by the efforts of the staff that it now holds the position of being the best and cheapest in the market, and that very considerable orders have been received for these lamps. That gentlemen is, I think, the whole of the story that I have to tell you. I have endeavoured to put before you clearly and in a few words the exact position of the Company, and I hope that the shareholders will agree that in this somewhat peculiar year in which we had exceptional difficulties to meet that we have done our utmost for the best interests of the share holders. I beg to move:—

"That the report of the Directors and statement of accounts to March 31 1893, be received and adopted."

Mr. R. E. B. CROMPTON, one of the Managing Directors, said that in rising to second the resolution just proposed by the Chrirman, he did not propose to say many words, as being Managing Director he was very largely responsible for the state of things and the diminished dividend, he did not want to put forward excuses. He would simply say that they had not made as good a year as they felt that they ought to have done. But the causes had been beyond their control. Bad trade generally had had a great deal to do with it as well as the expenses in connection with their boiler department—causes which were sufficient to account for the reduced dividend. But he could corroborate every word that the Chairman had said calculated to lead the shareholders to believe that this state of things ought not to diminish the profits in the future. He thought that everybody would admit that the period of depression in all kinds of trade which they were now passing through had reached the point at which they might at least hope for a turn of the tide, and he did not think that their Company would be unfitted to take advantage of the revival. It had been the great aim of the Managing Directors to look for every possible means of providing steady work for their Chelmsford shops, which would be in the nature of a backbone to the business. The manufacture and sale of dynamos had always been a part of that backbone. Although Crompton and Co. had for many years past been manufacturers of arc lamps, for the last six or seven years that had been quite an insignificant item in their business, the wages paid having been only a few hundred pounds per annum. So that now, as the Chairman had told them that they had suddenly as it were, developed the arc lamp, it made him, as a Managing Director, very hopeful that they had discovered a second string to their bow in the shape of the manufacture of an article which could be carried on in good as well as in bad times, and for which there would be an increasing demand when the normal state of affairs came round again. He thought, as to the demand for this new arc lamp, from what they had seen, that during the ensuing year it promised to yield something substantial towards the year's profit. He had no doubt they expected him say something regarding the heavy cost of the boilers. He was afraid he could not satisfy them much on this point. It was more in the nature of a pure accident that the boilers gave out as they did. They well knew that the demand, in consequence of the lighting at Chelmsford, added to the ordinary pressure on their works, would be very considerable last winter; but they did not reckon on the extreme badness of the water supply which damaged their old boilers before the new ones could be placed in position. Hurried work had to fill up the gaps between the failure of the old and the fixing of the new boilers which was a costly operation, and it was a very anxious thing for the Managing Directors to see money paid away weekly which they knew must come out of dividend. He thought, however, that they had taken steps to prevent the possibility of anything of the kind occurring again. Of course accidents might happen, but they had taken all possible means to prevent them. They had adopted the type of boiler best suited for very bad water, and in addition to that they had put down purifying plant. They had, moreover, taken advantage of this change to put up boilers which would enable them to use cheap coal, and thus the troubles which they had had in the past might be a source of profit to them in the future. He honestly believed that the cost of fuel would be much lower than it could have been with the old boilers, so that out of evil came good. They were watching this matter very carefully. They had a return drawn up every week, and from the commencement of the present year there had been a steady decrease of the expenses under this head. He could only say that the hard state of affairs affected the Managing Directors more than it did anyone else in the Company, and, therefore they had the sharpest spur put in them to see it improved as soon as possible. No one could regret more than he did that the shareholders did not receive their full dividend. He begged to second the motion.

Colonel WOOD suggested that they should increase the depreciation fund so as in future to cover any accidents that might occur to the boilers.

Mr. KITCHIN said that they must all agree that the report was an unfortunate one in many ways. A great deal of the eloquence of the Chairman and Mr. Crompton had been directed to the fact that their position was bad because trade was bad throughout the country. They all imagined that they were engaged in business which had felt that condition of things; but if there was one company which had not felt it it was Crompton and Co. (Limited). Consequently, the nature of the business and not the quantity of it had to do with their present position. He ventured to think that it was very largely due to unwholesome competition. But he would like to ask one or two questions in reference to that. First of all he would like to know whether the Chelmsford contract was paying; second, how long the lighting had been in progress there; third, at what date the boilers gave out; and fourth, what was the amount expended in making good the damage to the boilers. They had in the report a very vague statement that a certain amount had been spent, but he thought that the shareholders were entitled to ask what was the amount of extra expenditure which they had to face this year in making good the boilers so as to carry on the work—he hoped for 10 or 15 years—without further need for renewal. The sum, he observed, was to be charged to one year. Why this should be so he did not know unless there was some special reason for it. It was capital expenditure. He thought also that the enormous increase in the stock-in-trade deserved consideration. He understood that they were manufacturing dynamos available for future use. He would like to see some profit for the shareholders. He could quite understand that it might be necessary for a manufacturing company, in order to take a large contract to take an interest in other companies by taking their shares, but unless they were to get some return on the money they put in they had better be without the contracts dependent on such a proceeding. Therefore, he asked the Chairman to be kind enough to say what the investments of the Company were, and whether he thought it necessary to have such a large stock-in-trade.

Mr. BLAXLAND asked how they paid the interim dividend in view of the facts which had just been disclosed.

The CHAIRMAN said that the Directors were always obliged to any gentleman for criticising their acts in the friendly spirit in which it had been done that day. In reply to the question put by Colonel Wood, he understood that gentleman to say that they ought to increase the amount for

Digitized by Google

depreciation so as to cover such accidents as might occur to the boilers. He believed that the boiler plant was insured, and the depreciation was put down at the full amount considered necessary, it had been increased this year by £500. It was quite sufficient to meet all ordinary accidents and wear and tear. He did not quite say that it would cover every accident; but the suggestion of the auditors was followed in the matter. Mr. Kitchen had pointed out that it was not so much bad times as the nature of their business that adversely affected them. The business, however, showed a very satisfactory result. If they took their gross returns they were very satisfactory. If it had not been for the exceptional circumstances which had been referred to they would have had a very satisfactory year; but he thought that they were justified in pointing out that they had succeeded in doing what they had done in spite of bad times and bad trade. As to the Chelmsford contract, the lighting was going on satisfactorily. The public lighting is not profitable but the private lighting shows a very fair margin and the number of lamps is steadily increasing. They hoped that in a short time it would be put on fair commercial lines—perhaps within this year. With regard to the cost of the break down of the boilers, they had had to spend a considerable amount for temporary work so as to enable them to carry on the business, in spite of what had happened. He thought that it put them to an outlay of about £2,000, which could only be dealt with as temporary expenditure. That was entirely apart from an expenditure of capital. The fresh boilers and water-purifying plant were entirely outside that. The question how they should charge the amount was one which greatly exercised his mind, and he was not sure that Mr. Kitchen would not support him in charging it over a term of years. He was quite sure that they would be justified in doing it. Still, they thought that they had done the wiser thing in facing the whole difficulty this year, although it did reduce the dividend. With respect to the increase of stock, that was a question which cut both ways. They had been trying for some time to have sufficient stock in hand to meet orders when they happened to get one in a hurry, so as to be able to carry it out promptly. If they were low in stock there was a danger of losing business. Whether they had reached the medium of having not too much or not too little it was difficult to say; but, at all events, it was satisfactory to know that they had sufficient finished machines in stock, which would enable them to deal with orders as they came in, and to secure others which they might otherwise lose. With regard to the investment of shares in other companies, no one felt more strongly than he did, that they ought to be very careful when they dealt with that matter. It was quite true that the requirements of the trade and the general business done might lead them to obtain orders by so investing in other companies, and it was sometimes an advantage for this reason to have an interest in these; but they were very adverse to such a policy unless they saw their way to get some good return for the outlay. The date at which the boilers gave out was January last, when they had no idea that anything of the kind was to occur. The question of the interim dividend had been raised by Mr. Blaxland. When they dealt with the interim dividend they could deal only with the figures before them. As he had already pointed out, and he hoped satisfactorily shown, if it had not been for the exceptional circumstances referred to their net receipts this year would have been exceedingly satisfactory. The difference between the net and gross receipts, as far as the dividend was concerned, was brought about by these causes, and these exceptional circumstances were not known at the time the interim dividend was declared. It was quite impossible for the Board to foresee them. They had power by the Articles of Association (Section 85) to pay the said dividend. As far as the Preference shares were concerned, as he had said at the beginning of the meeting, their interest was a cumulative interest, and it was only a question of postponing the payment of 1 per cent. for a year, when their claim would be prior to that of any others. There was a reserve fund upon which they could have drawn for this purpose, but they thought that it was better not to encroach too much on it.

Mr. KITCHIN: There is one more question I should like to ask before you put the resolution. I notice that the Auditor's certificate is qualified by the words "subject to our report of this date." Now this may mean there is something concealed which we ought to know, and I should like an explanation.

The CHAIRMAN: In the former year's certificate, the Auditor's words were "as per" instead of "subject to" their report. He did not know what the difference really was, but the words "subject to" certainly implied a reservation. He thought it would be more satisfactory if he read the report, which was as follows: "We beg to report having completed the audit of accounts for the year ended March 31st last, and hand you herewith the balance-sheet to that date with our certificate attached. We notice a large increase in the Company's holdings in various undertakings, which have been from time to time fostered or supported by your Company. It is not possible for us to exercise a judgment upon the value of such assets. But we desire to call attention to the fact that many of these have not yet reached a dividend paying condition, and are, therefore, *prima facie*, not worth their par values. We also notice that there are large amounts due from these same companies, which stand under Sundry Debtors in your balance-sheet. The stock has been certified to us by Mr. James W. Rooke, foreman of the stores department, and the capital expenditure, together with the expenditure on experimental work by Mr. Crompton, one of the Managing Directors." That is all there is in the document. He had already explained about the Chelmsford Lighting Company, and no doubt other companies which are new undertakings will also pay shortly—of course, the moneys due from those companies under the contracts with them are included in Trade Debtors.

The motion was then put to the meeting, and carried unanimously.

The CHAIRMAN next moved—

"*That a dividend at the rate of 2s. 6d. per share for the half-year ending March 31, 1893, making, with the interim dividend already paid, 6 per cent. per annum, be declared and paid on the Preference shares.*"

Mr. J. F. ALBRIGHT seconded the motion, which was agreed to *nem. con.*

On the motion of the CHAIRMAN, seconded by Mr. CROMPTON, the retiring Director, Mr. H. H. J. W. Drummond was unanimously re-elected.

Mr. R. PAYNE proposed, and Colonel JAMIESON seconded, the re-appointment of the auditors, Messrs. J. H. Duncan and Co., which was also agreed to without a dissentient.

A vote of thanks to the Chairman, moved by Mr. T. R. TUFNELL, and seconded by Colonel JAMIESON, who said the explanations given were perfectly satisfactory, was cordially passed, and the CHAIRMAN having briefly acknowledged it, the proceedings ended.

Electrical Power Storage Company (Limited).

The following report is issued by the Directors of this Company for the period ended May 31st last:—

The profit, after payment of general expenses, management, &c., is £5,245. 2s. 2d., from which the Directors have, in deference to the wishes of the Auditors, deducted a sum of £1,500, writing that amount off the patent account, leaving, with a balance of £626. 7s. 7d. from last year, an amount of £4,371. 9s. 9d. available for distribution, out of which the Directors recommend the payment of a dividend of 5 per cent., leaving £158 19s. 5d. to be carried forward. Provision has also been made for maintenance of buildings, plant, tools, &c., by writing off the sum of £2,083. 18s. 9d. The Directors are pleased to be able to report the continued success of the Company's operations; a considerable reduction in the selling price of its manufactures has been made, for the purpose of bringing storage batteries into more general use.

Particular attention has been devoted to securing such inventions as would tend to cheapen production while combining maximum efficiency and durability; and with this object several new patents have been acquired, and sole licenses for others have been obtained. Constant attention has been also given to the development of electric traction, for which the Directors expect a considerable demand will shortly arise. The Company and its licensees have been successful in patent litigation abroad.

The fourth ordinary general meeting of the Company was held at the offices, 4, Great Winchester-street, E.C., on Thursday last week, Mr. J. Irving Courtenay (Chairman of the Company) presiding, and we have been supplied with the following account of the proceedings:—

"The SECRETARY (Mr. J. W. Barnard) having read the notice convening the meeting,

"The CHAIRMAN said: In making some observations upon the accounts I desire to point out that the difference in the balance carried forward from the trading account this year and last year is mainly owing to proper deductions having been made in balancing the trading account, the discounts and other charges having been deducted before bringing forward the balance. The gross amount of orders is larger than last year, but owing to the reduction in price, and increased discounts to the trade, the cash received is rather less. But you will also notice that, in consequence of economies having been introduced into the management and into the manufacture, the net profits are practically the same, because from the amount of the profits we have written off this year £1,500 towards depreciation of patents. The Company is selling more of its manufactures than it did, and thus it is increasing its goodwill and obtaining a larger business with the public, because the objection taken in past years to the high price of accumulators have been to a considerable extent removed by the reductions in question. You are all aware of the depressed condition of trade, and that the electrical industry, like all other businesses, is suffering from the depressed times, but I am glad to say that the E.P.S. Company has done well, in spite of this almost unprecedented depression. We do business with all the leading firms, and the result is that whatever business is going we get a share of. We have competition to contend against, and no doubt shall always have, but I think by the improvements that have actually been made, and those we have in contemplation, and by the economies these will effect in the manufacture of the batteries, we shall be able to hold our own. We are, as you are aware, also acquiring patents for details in manufacture, and so in reality, though the basic patents are growing older, we are strengthening the position by these newer patents. One of the most vital questions for the E.P.S. Company is traction. You know that this Company associates itself almost entirely with what is called self-contained traction, and has endeavoured to develop it, though up to the present not with the results we aim at; but we do not for one moment despair of ultimate success. A portion of the expenditure in legal charges was incurred in what at one time looked a hopeful business, in endeavouring to obtain an Act of Parliament in an important provincial town for an electrical tramway. We failed because we could not get the necessary agreements confirmed in time for Parliament, and so the Bill was dropped. But we are persevering (not in that particular locality) with self-contained traction, and you have heard of a small company that has been formed—I refer to the Pioneer Electric Carriage Company—to develop a form of traction with novel features, among which is the pneumatic wheel. Some few of our friends have put their money in to test it, and, if successful, it will be a great benefit to the E.P.S. Company, and bring a wide demand for its batteries—such is the interest the E.P.S. has in the welfare of that concern. I do not think I need trouble you with any further remarks, and conclude by saying, so far as is possible to see ahead in these days, I entertain no doubt that the E.P.S. Company will continue to prosper. He then moved, 'That the Directors' report and statement of accounts to May 31, 1893, be and are hereby approved and adopted, and that a dividend of 5 per cent. on the paid-up capital be declared, payable on August 24, 1893.'

"Sir DANIEL COOPER seconded the motion.

Digitized by Google

"Mr. J. W. BARCLAY: I do not intend to offer any criticism of the accounts, but to refer to a point which invites attention, viz., the use of accumulators for propelling carriages. Shareholders of the Pioneer Electric Carriage Company are endeavouring, at their own expense, to develop a system of self-contained traction for ordinary carriages. If the attempt prove successful a very wide field for the use of accumulators will be opened up. Meanwhile, the problem we have before us is to prove that this new method of locomotion is useful commodious, and economical. The operation of the Pioneer Company should certainly encourage shareholders to be hopeful for the future of the electric storage battery industry.

"The resolution was carried unanimously, and the retiring Director, Sir Daniel Cooper, Bart., G.C.M.G., having been re-elected, other formal business was concluded.

"In responding to a vote of thanks, the CHAIRMAN observed: I should like to say I have waited for this opportunity of expressing our indebtedness to Mr. Frank King and the staff for the keen and intelligent energy with which they have pushed the business of this Company. The Directors will bear me out when I say that Mr. King and his staff spare no effort to promote in all directions the interests of the E.P.S. Company.

"Mr. FRANK KING: On behalf of the staff and myself I beg to thank the meeting and the Chairman. It is our duty to convince engineers and others that the Secondary Battery, as manufactured by this Company, is the very best battery, for all purposes, they could possibly desire. We have been successful in this, and it is a great satisfaction to us to know that our efforts are appreciated.

"The proceedings then terminated."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

FRANK W. CLARK AND CO. (LIMITED).—This Company was registered on July 26th, with a capital of £10,000, in £1 shares, to (*inter alia*) acquire and deal with patents and inventions relating to the manufacture, purification, improvement, consumption, and distribution of gas or electricity.

GENERAL ELECTROLYTIC PARENT COMPANY (LIMITED).—This Company was registered on July 31st, with a capital of £24,000 in £1 shares, to ratify an undated agreement with James Hargreaves, Thomas Bird, John Hargreaves, Albert M. Gibson, and Arthur C. Bulkley Praed, for the acquisition of patents for "Improvements in Electrolytic Cells and Diaphragms," and for "Improvements in the manufacture of alkali and in apparatus therefor," and provisional specifications for "Improvements in the production of alkali and in apparatus therefor, the said apparatus being for electrolysis generally," for "Improvements in and in the making of electrolytic apparatus," for "Improvements in the electrolysis of iodides, bromides, nitrates, and other salts," for "Improvements in the electrolysis of chlorides, iodides, bromides, nitrates, and other salts and apparatus therefor," and to develop and turn to account the same.

INCANDESCENT ELECTRIC LAMP COMPANY (LIMITED).—This Company was registered on July 25th, with a capital of £25,000 in £10 shares, to carry on the business of manufacturers of, and dealers in, electric lamps, fittings, appliances, and materials, to generate, accumulate, distribute and supply electricity, for the purposes of light, heat, motive power, &c., to construct, lay down, establish, fix, and carry out all necessary cables, wires, lines, accumulators, lamps, and works, and generally to carry on the business of an electric light, heat, and power supply company, in all or any of its respective branches. The subscribers are:—

	Shares.

E. Howe, 1, Lowndes-square, S.W.	10
T. H. Riches, Yelverton, South Devon	100

The first Directors are James Fraser, Gustav Binswanger, and C. J. Robertson (Technical Director).

ALLEN, EVERETT, AND SONS (LIMITED).—When the annual return of this Company was filed on June 29th, 10,000 Preference and 12,000 Ordinary shares of £10 each had been subscribed for, 3,300 of the Preference and 4,000 of the Ordinary had been issued as fully paid, while the full amount had been called on the 6,700 Preference and £8 per share on the 8,000 Ordinary shares. The calls paid amount to £131,000. The nominal capital is £300,000, divided into 10,000 Preference and 20,000 Ordinary shares of £10 each.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—Mr. Justice Vaughan Williams on Wednesday ordered the voluntary winding up of this Company to be continued under the supervision of the Court.

GREENWOOD AND BATLEY (LIMITED).—The annual return of this Company made up to July 1 has been filed. The nominal capital is £400,000, divided into 14,000 £7 per Cent. Cumulative Preference, and 26,000 Ordinary shares, all of £10 each, 11,065 of the former, and 18,052 of the latter class have been taken up, of which 2,666 Preference, and 4,666 Ordinary, have been issued as fully paid. Upon 9,600 Preference and 16,850 Ordinary the full amount has been called (or considered as such), while upon the remaining 1,456 Preference and 1,252 Ordinary shares £3 per share has been called, resulting in a total payment of £198,834.

HERCULITE AND ELECTRICAL MANUFACTURING COMPANY (LIMITED).—The statutory return of this Company, made up to May 25th, has been filed. The nominal capital is £12,000, divided into 4,000 Preference and 8,000 Ordinary shares of £1 each. 1,953 of the former and 4,000 of the latter (issued as fully paid) have been taken up, the full amount having been called on the Preference shares. The calls paid amount to £1,958 (which includes a sum of £25 paid on 50 forfeited Preference shares), leaving £25 in arrears.

HOME TELEPHONE COMPANY (LIMITED).—The return for 1893 states that the whole capital of £500, in £5 shares, has been subscribed for, £2 per share called, and £200 paid.

INTERNATIONAL OKONITE COMPANY (LIMITED).—The return of this Company, made up to January 24th, was filed on June 26th. The whole nominal capital of £340,000, divided into 17,000 Ordinary and 17,000 Preference shares of £10 each, was allotted; 11,332 shares have been issued as fully paid, and the full amount called on the remaining shares. The calls paid have realised £225,665, leaving £1,015 in arrears.

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—The statutory return of this Company, recently filed, shows that out of a nominal capital of £10,000, in £1 shares, 4,083 shares have been taken up, and 3 300 issued as fully-paid. The full amount has been called on the remaining 783 shares, resulting in the payment of £728, and leaving £55 in arrears.

LATIMER CLARK, MUIRHEAD AND CO. (LIMITED).—The annual return of this Company made up to July 21st has been filed. 4,709 £10 shares of a nominal capital of £100,000, in shares of £10 each have been taken up, the full amount called, and all calls paid.

LONDON BATTERY COMPANY (LIMITED).—At meetings held on July 11th and 26th a resolution was passed and confirmed that the Company should be voluntarily wound up, and that Mr. H. G. Ellis be the liquidator.

J. H. PICKUP AND CO. (LIMITED).—The annual return of this Company, made up to June 14th, has been filed. The 3,000 shares of £5 each, constituting the nominal capital, have been taken up, 800 being issued as fully-paid, and £3 per share called and paid on the remainder.

THORNEBURRY MINERS' SAFETY LAMP COMPANY (LIMITED).—It was resolved at meetings held on June 27th and July 18th to wind up the Company voluntarily, and Mr. F. Newton, 9, Warrington-crescent, Maida Vale, was appointed liquidator.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 30th were £822, as against £735 for the corresponding period of last year, being an increase of £87. The total receipts for the half-year amount to £3,425, against £3,021 in the corresponding period of 1892, being an increase of £404.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—A half-yearly dividend at the rate of 8 per cent. per annum is proposed by the board. The estimated traffic receipts of this Company for the month of July are £3,000, as compared with £3,194 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of July amounted to £62,317, and to £49,117, in the corresponding period of 1892, an increase of £13,200.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of the Eastern Extension, Australasia and China Telegraph Company (Limited) for the month of July, 1893, amounted to £45,376 and to £41,714 in the corresponding period of 1892; increase, £3,662.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The ordinary half-yearly meeting will be held at the Law Association Rooms, Cook-street, Liverpool on Tuesday next, the 8th inst. We gave an abstract of the Directors' Report in our last issue. A special general meeting is to be held immediately afterwards, when a resolution will be submitted authorising the issue of 4,500 Five per Cent. Preference Shares of £10 each, the unissued portion of an authorised issue of 12,000 Preference shares.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow the following securities of the National Telephone Company (Limited) to be quoted in the Official List:—Further issues of 25,730 Ordinary shares, Nos. 453,868 to 484,597; 28,284 Five per Cent. Non-cumulative Third Preference shares, Nos. 90,951 to 119,234; £198,540 Four and a-Half per Cent. Debenture stock.

Digitized by Google

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY.—Coupon No. 6 of the Five per Cent. First Mortgage Debentures, due July 31st, will be paid from that date at the Consolidated Bank, Threadneedle-street, or at the banking house of Westendorp and Co., Amsterdam.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 28, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,784.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 795.—Vol. XXXI. FRIDAY, AUGUST 11, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

At the last meeting of the Glasgow Town Council it was cided by the by no means overwhelming majority of 27 to 21 adopt the recommendation of the Telephone Committee at a municipal telephone licence should be applied for. One ponent of the scheme characterised it as "rash and quixotic," d the data upon which the recommendation was based as crude and problematical," and the answer was that an appli- tion for a licence committed the Town Council to nothing particular, and that the only way to meet the National lephone Company in regard to the protection clause it had cceeded in getting inserted in the Tramway Bill was to ke the step recommended. Of course, if the municipal tele- one licence is to be used merely as a means of securing the peal of that clause the argument is good enough. On the her hand, if the Corporation mean business, reliable estimates om a competent expert, a promise of active adhesion on the rt of the National Company's present subscribers, and careful consideration of the attitude to be assumed in view of rate-cutting policy being adopted by the Company should ccede, not follow, an application for a licence.

The merits of a new process are sifted the more in pro- rtion to the catholicity, so to speak, of the criticisms which calls forth. When an inventor proposes a new mode of otive power for electrical supply he runs across fire from engi- ers of every interest. He is assailed on one hand by the lvocates of existing modes of motive power—the steam, the s and the oil engineers. He is assailed on the other hand by e advocates of systems of lighting and power distribution hich are not electrical. So has it been, to particularise, with e inventors of, and those interested in, the various forms of ater-gas, such an one for instance as Dowson gas. The e of this well-known gaseous fuel has been subjected to ch universal criticism that electrical engineers may con- atulate themselves on ultimately getting at its real value. he latest to enter—perhaps we should say re-enter— e lists is Mr. Denny Lane, who has a twofold interest the prosperity of the coal gas industry since he would mbine with gas lighting electric lighting by means of s engines, and who is, on that account a "foremost eman" worthy of Mr. Dowson's steel. To the use of the -called "producer" gas Mr. Lane opposes no less than eleven objections, some of which, at any rate, are of no little importance. The very much lower thermal value of a nitrogen-diluted water gas, compared with coal gas, would necessitate, according to Mr. Lane's calculations, mains having six times the section, gas-holders having four times the capacity, and a very much larger engine, in order to arrive at the same amount of distributed power. These are a very serious set off to the high fuel economy of the water gas system; and they raise points which no engineer, whose business it may be to select a system of power distribution can afford to overlook. But all this is rather beside the mark; beside Mr. Dowson's mark, if we properly understand it. In his valuable paper read before the Institution of Civil Engineers last session he said nothing about distributing his gas by mains, and is, no doubt, ready to admit most of the so-called "objections." The fact remains that Mr. Dowson claims that he can run a 100 H.P. electric light plant at a less cost than anyone else. He has challenged the world to compete with him, no one has responded, and like a champion athlete "against time" he is going to carry out the trial, and demonstrate at his own expense the validity of his claims.

We can only characterise as bold the scheme of power transmission in Switzerland, of which we give an account this week. There is nothing unusual or exceptionally difficult, of course, in the transmission through aerial conductors of about 400 H.P. over a distance of some 20 miles. Neither is there, we think, any very great advance made in the getting of 78 per cent. over all efficiency under these conditions. But the boldness of the scheme enters into the details in which it is worked out; into the system adopted, and the types of machines chosen. The desirability of transmitting the power at as high a pressure as possible need not be referred to; but the desirability of selecting Gramme-wound armatures coupled in series with a total pressure of 6,600 volts is not one which would be likely to strike every engineer at first or even at second thought. We understand that these same closed-coil armatures were run for some time as a test, delivering 10 amperes at 4,700 volts per machine. Whether or no it was the intention of the engineer, M. Goichot, to run the plant permanently at this voltage, we cannot say; but we can well understand the advisability of adopting the but slightly less risky voltage which is now in use. It will be interesting to see how the surfaces of the large commutators are found to wear, and to know whether any serious difficulties arise owing to sparking and flashing over.

Digitized by Google

THE substitution of electricity for horses on the tramways of Brooklyn and other American towns is, as might have been anticipated, telling upon the number of tram horses employed. What the effect of the continuation of this elimination will be upon the genus *equus vulgaris* it is not the immediate concern of the electrical engineer to inquire. The domestic horse has been threatened with extinction more than once before, but will, no doubt, still find his place in the economy of civilisation. On the other hand, the effect of this substitution upon the comfort of the community is one to which electricians have every interest in inviting attention. One of the most abominable nuisances of our streets in summer is the dust, and in the winter the mud. Water added to the one makes the other; so we have only to discover the source of dust to find the origin of both these evils. Without doubt, nearly the whole of street dust is directly due to the presence of the domestic horse; for what his fodder does not produce is caused by the tramping of his feet on the road material. A careful examination of a sample of road dust collected on an asphalte road will be found to be almost wholly composed of particles of hay and horse food; on a wood-paved road it consists partly of splints of timber detached by the horses' hoofs; while on the less common macadamised road there is, of course, a considerable percentage of mineral matter. In fact, in whatever proportion the domestic horse becomes eliminated by the electromotor, it will be found that the city dust and the greater part of the street noise, will in the same proportion disappear.

THE wily ancient Egyptian priests who designed automatic machines for dispensing holy waters to those who were about to enter the temples of Osiris, Isis, or Horus, set a fashion which—long buried—has in these modern times been revived, and is now actually being applied to the dispensation of artificial light. The "penny-in-the-slot" meter has not, as yet, fastened itself upon electric mains; though it is already in use in a few railway carriages, and we believe to a limited extent for doling out coal gas. Possibly, by the adoption of this method, electrical engineers may solve the difficulty of differential charges; a meter being designed which with one mite at noon or two mites at night would pass a joule and a decimal through the circuit. What is really wanted, however, is a contingent of MAXWELL'S "sorting demons," who, stationed inside the meters, would tilt over the levers to the higher tariff at sunset.

Electrical Bills in Parliament.—The Hampstead, St. Pancras, and Charing-cross Railway Bill was read a third time in the House of Lords last week, and passed.

Cable Interruptions and Repairs.—

	Interrupted.	Repaired.
Paramaribo—Cayenne	April 15th	August 7th.
Aden—Zanzibar	August 9th	—

Southport.—At a special meeting of the Town Council last week it was resolved that a high-pressure alternating system of electrical supply should be laid down for the central area of the town, at an estimated cost of £13,000.

Bolton.—On Thursday last week Major-General Crozier, one of the inspectors of the Local Government Board, held an inquiry into the application of the Corporation for sanction to borrow £75,000, of which £40,000 was for the purpose of electric lighting.

Aberdeen.—There were 65 applicants for the appointment of Electrical Engineer to the Aberdeen Town Council, and Mr. E. T. Ruthven Murray, electrical engineer of Larne, County Antrim, has been appointed. The salary of the appointment is £250 a year.

The Trans-African Telegraph.—According to the Cape Town correspondent of *The Times*, the contractors are starting out to begin the construction of the first section of the Salisbury-Tete overland telegraph. Contracts reaching to the Nyassa have already been signed.

European Electric Traction Development.—The extent of European electric railway work, says the *Electrical Engineer* of New York, may be best expressed by referring to the fact that Boston alone has a greater electric railway equipment both in miles of road and number of cars than the whole of Europe.

Telephone Poles at Chesterfield.—At the last meeting of the Town Council, Ald. Wood moved that notice be given the National Telephone Company to remove all their poles now standing in the streets and thoroughfares, and that the Corporation require the wires to be laid underground. The resolution was carried.

A Wiremen's Strike.—The strike of the bricklayers and electric wiremen who were at work on the annex to the Mutual Life Building on Liberty-street, near Nassau-street, still continues, says the *Electrical Engineer* of New York. Forty-eight bricklayers, and eight electric-wiremen have been out, both sides contending that they are entitled to the work of making holes in the walls for the wires.

Cooling Bearings.—As a means of cooling bearings, an American suggestion is that in any place where air-compressors are used, or where an air supply is convenient, it would be well to conduct a pipe so as to blow air upon the heated bearings. Air has an additional advantage in the fact that it cools in expanding so as to still further aid in the cooling of boxes where this scheme is applied.

The Forthcoming Meeting of the British Association at Nottingham.—The Presidents of Sections A and G of the British Association this year will be Mr. R. T. Glazebrook and Mr. Jeremiah Head respectively. In Section A it is possible that the following matters will be discussed:—The establishment of a national physical laboratory, the publication of physical papers, magnetic and other units, the mechanical connection between ether and matter.

The Hobart-Town Electric Tramway.—A definite stage has been reached in the construction of the electric railway at this town. Recently the machinery at the generating station was put on a trial run. There are three Siemens-Willans steam dynamos, running at 350 revolutions, and having an output of 125 kilowatts. The boilers are designed for 60 H.P. at 160lb. pressure, and are of the Marshall multitubular type; there are four of these boilers, which are fed hot from two Marshall's feed heaters, by means of Worthington pumps. The overhead trolly system is to be used, each car being provided with two 15 H.P. Siemens electromotors.

The Use of Telephone Trunk Wires.—In the House of Commons last week Captain Bagot asked the Postmaster-General whether, in case the Post Office purchased from the National Telephone Company their trunk lines as contemplated, he would provide that all telephone exchanges having the use of such trunk lines in connection with their own exchanges should give facilities to other exchanges, irrespective of their ownership, for communication with their subscribers through such trunk lines. The Postmaster-General replied that the subject had been carefully considered, and the agreement now in course of negotiation provided for such facilities.

The Strand Lighting.—At the meeting of the Strand District Board of Works, last week, it was stated in moving the adoption of the report of the Works Committee that the Committee had had before them a scheme for the electric lighting of the Strand by the Metropolitan Electric Light Company, who propose to substitute for the present 67 gas lamps, costing £473. 11s. 11d. per annum, 22 arc lamps at a yearly cost, including renewals of carbons, cleaning, and all

Digitized by Google

attendance, of £1,195 per annum, on the understanding that half that number of lamps would be extinguished at midnight. The Committee could not advise the Board to adopt the electric lighting until it became much cheaper.

Stafford.—At the quarterly meeting of the Town Council held last week the Electric Lighting Committee recommended that the scheme proposed by Mr. Bell, gas engineer, and endorsed by Dr. John Hopkinson, should be carried out, and that application should be made to the Local Government Board for authority to borrow £20,000, of which £12,000 was to be spent at once. The proposed price is 7d. per unit, and the system recommended is the continuous-current, low-pressure one. After some discussion the report of the Committee was carried by twelve votes to eight. On the recommendation of the Gas Committee, it was resolved that sufficient land should be set apart at the gasworks for a site for the electricity supply station.

Cheltenham.—At the meeting of the Town Council, on Tuesday, Mr. George Norman (Chairman of the Electric Lighting Committee) brought up the Committee's report, which recommended the adoption of the high-pressure alternating-current system of electric lighting for the town, the supply to be undertaken by the Corporation, using the ash destructor site for the station. Mr. Norman explained that Mr. W. H. Preece had given the Committee the benefit of his advice. A suggestion was made that the vote on the subject should be postponed for a month, in view of the smallness of the attendance at the meeting. The suggestion was not acted upon, and the Committee's report and recommendation were adopted by ten votes to one.

Lightning.—During some manœuvres at Nevesinji, in Herzegovina, last week, a group of Austrian officers was struck by lightning, one being killed and five injured. During the thunderstorm of Wednesday night considerable damage was done to life and property in various parts of the United Kingdom. Mr. Owen's flax mill at Ballymarlow, near Ballymena, Co. Antrim, was fired by lightning, and part of the premises was destroyed, together with a quantity of stored flax. In Wales Mr. S. J. Griffith Morswyn, a well-known Welsh poet, was returning to his home in the suburbs of Holyhead, when, as is supposed, he was struck by lightning. This morning he was found stretched on the ground in an unconscious condition, and died without having regained consciousness.

The Telephone in Denmark.—The Copenhagen Telephone Company will, says our correspondent, remove in about a year's time to a new central exchange which is being specially built for it, and which will be exceptionally well appointed in every respect with accommodation for 10,000 subscribers. The new exchange will be lighted by arc lamps and bids fair to be one of the best in existence. The multiple boards will be of a new and improved construction. In the meantime it has been necessary to extend the existing exchange, where the daily number of conversations is about 30,000. Experimental telephonic connection has recently been established across the Great Belt, a distance of some 20 miles, an existing submarine cable being used. The result was quite satisfactory, and the two islands of Zealand and Fünen will no doubt soon be in telephonic connection.

The Proposed Pacific Cable.—According to the daily papers Mr. Patterson, the Victorian Premier, has addressed a protest to the Governments of Queensland and New South Wales against their committal to a cable to New Caledonia, thus hindering the project for a British cable to Vancouver by any other route. Mr. Patterson protested against being compelled to accept the New Caledonian route without consultation, and said he should be glad to learn that Queensland and New South Wales were still free to contract for a main Pacific cable otherwise than *viâ* New Caledonia. No reply has been received to these representations, but Mr. Patterson has written to the Imperial and Canadian Governments disclaiming responsibility for the selection of the New Caledonian route, and both the New Zealand and Tasmanian Governments have expressed agreement with the position he has assumed.

Australian Mica.—At one time, says *Industries and Iron*, great hopes were centred upon the mica industry at the McDonnell Ranges, South Australia. Unfortunately, what promised to be a profitable industry languished through the fall in the price of mica and the difficulty of transportation to foreign countries. A large proportion of the consignments to Adelaide broke into small pieces on being trimmed, and these fragments were believed to be worthless. It is now, however, thought that they will command ready sale. In consequence, fresh parties are starting from Adelaide for the McDonnell Ranges to re-open workings which had been abandoned. The mica has to be carried some 500 miles on camels to Oodnadatta Station, the present terminal point of the great overland railway being constructed by the South Australian Government. Thence it is carried by train to Port Augusta and shipped to the most profitable of the world's markets. The great want on the field is a man who is accustomed to practical working of such deposits. At present an expert judge of mica is at McDonnell Ranges, and is purchasing mica there at rates very profitable to the miners.

The City and South London and Liverpool Overhead Railways.—The following comparative figures with regard to the City and South London and Liverpool Overhead railways may be of interest. It is to be observed, however, in connection with the locomotive and generating expenses per train mile that whilst on the London line the trains consist of three cars and a locomotive, at Liverpool each train consists of only two motor-cars; at Liverpool, moreover, the trains are run under a contract with the Electric Construction Company. The figures for total capital expenditure, capital expenditure per mile of line open, and passengers carried, are given in round numbers:—

—	City and South London Railway.	Liverpool Overhead Railway.
Length of line open	3½ miles	5½ miles
Total capital expended on line open	£873,000	£528,000
Capital expenditure per mile of line open	£280,000	£103,000
Present rate of passenger traffic per annum	6¼ million	4⅓ million
"Loco" and generating expenses per train mile	6·48d.	4d.
Passenger earnings per train mile run	24·7d.	26·6d.

Provisional Orders Granted.—In the last report presented to Parliament by the Board of Trade it is stated that 18 applications for Electric Lighting Provisional Orders were received in time for consideration during the current Parliamentary Session, 11 of these being made by local authorities. The following is a list of the Orders actually granted in the provinces.

Altrincham	Manchester Edison-Swan Company.
Barnet	Local Board.
Beckenham	Local Board.
Bridgend	Local Board.
Colchester	Corporation.
Eccles	Corporation.
Newcastle-upon-Tyne	Newcastle-upon-Tyne Electric Supply Company.
Newmarket	British Electric Light Company.
Partick	Commissioners of Police.
Reading	Reading Electric Supply Company.
Taunton	Corporation.

In the metropolis Orders have been granted to the Vestries of Hammersmith, Hackney, Islington, and Poplar. Sanction has also been given to the transfer of municipal Orders to companies at Cambridge and at Hove. Including the Orders just granted, there are now no less than 170 in force, of which 112 belong to local authorities. Of the 69 Orders granted in 1883 only 7 remain in force in 1893; these relate to Bradford, Brighton, Bristol, Nelson, Richmond, St. Pancras, and Greenock, the first six being now worked by the local authorities.

Central Stations in France.—A recent number of *l'Industrie Electrique* gives a complete table of the French provincial central stations for electric supply, and a map showing their distribution. The total number of these stations is 255, of which 209 are on the continuous current system. One of the most notable features is the large proportion of stations in which water-power is either entirely or partially used for driving the dynamos. Out of the total of 255 stations entered in the table, there appear to be as many as 160

Digitized by Google

employing hydraulic power. Most of these, however, are only small country-side stations of less than 100 H.P. The number of stations run by gas engines is also considerably in excess of those to be found in this country. There are 17 of these, of which only one or two exceed 100 H.P., and the majority are very small. Another notable feature is the latitude which is given to the term "central station"; for we find that the smallest of the French stations has only 5 H.P., and the average is only 120 H.P. This miniature station is at Darnetal, in the Department of Seine-Inférieure, and is driven by hydraulic power. The largest provincial station, one of 2,000 H.P., is at Toulon; and Rouen, with a station of 1,200 H.P., takes the second place. There are 68 stations in course of construction.

Artificial Draught.—Everyone familiar with the management of steam boilers is agreed that no artificial draught is in all respects so satisfactory as that produced by a good chimney. The chimney draught is always at hand and ready for its duty, and the fireman has simply to pull open the damper to bring it into operation. There is, says the *Engineering Record*, no machine connected with it to require attention, nothing to get out of order, and there are no running expenses required to maintain it. Although these things cannot be said of a draught which is produced by mechanical appliances, there are some features connected with artificial draught which commend it to the engineer and to those who have the care of a steam plant. We refer to the system embracing an exhausting fan placed in the smoke flue, which is operated by an independent engine. Looking at the subject from an engineer's point of view, the use of the mechanical draught enables the heat of the waste gases to be utilised without sacrificing the draught power. This advantage may assume great importance in obtaining economy in the consumption of fuel, for a reduction of every 15deg. to 20deg. in the temperature of the gases by the use of a feed-water heater in the flue secures a saving of 1 per cent. of fuel. Apart from this it must be agreed that the flexibility of a system of artificial draught is an advantage which under many circumstances which arise in the working of a plant of boilers has much to commend it. If for any reason an unusual force of draught is required to maintain the necessary supply of steam, the fireman simply gives the throttle valve of the fan engine an extra turn, increasing its speed and securing the desired increase.

Massachusetts Institute of Technology.—We have received a well-written and artistically illustrated pamphlet, prepared in connection with the Chicago Exhibition, giving a brief account of the foundation and character of the Massachusetts Institute of Technology. This is the largest scientific and technical school in the United States and one of the largest in the world. From a recent report it appears that during the last session no less than 1,060 students of both sexes took advantage of the courses of technical and scientific instruction, which were provided; the various classes being superintended by a staff of 125 teachers. There are 13 separate courses, each covering four years of lectures and laboratory instruction. The equipment for electrical engineering and allied studies is on a most magnificent scale, and includes three spacious and well-stocked laboratories, besides the lecture rooms and a set of technical libraries containing nearly 27,000 volumes. The allied sciences of chemistry, mathematics, and mechanical engineering appear to be equally well provided for; so that, with the proper amount of time at his disposal, the electrical student can either master completely the details of one special branch of his calling or he can attain great breadth of information by "all round" study. One of the avowed objects of the Institute is "to make the pupil observant, discriminating, and exact;" so that it aims at combining the mental education of the universities with the instruction of the technical institutions. Success in this direction is, it appears, possible without, on the one hand, the necessity for teaching so called "useless knowledge," or, on the other hand, adopting the practice of labelling a technical institute with the misleading and ambitious name of university.

The Telephone in Scandinavia.—The means of telephonic communication within and between the Scandinavian countries are, says our Copenhagen correspondent, being steadily and continuously extended. The necessary funds have now been voted both by Sweden and Norway for telephonic connection between the two countries, and the Stockholm-Christiania line will be forthwith taken in hand. The line will be 350 miles long, of which only 90 miles come in Norway and in Sweden. The existing telephone wires can be used for the greater portion of the Swedish section. In Norway 3·3 millimetre copper wire will be used, and the same poles will be used where possible, as are already used for the telegraphs, but to avoid induction the telephone wires will be twisted. In Sweden this line will be worked by the State; in Norway it has been left in the hands of the Christiania Telephone Company. The fee for a three minutes' conversation will be one shilling, eighteenpence, and two shillings, according to the distance included on the Swedish side of the frontier. Should the Stockholm-Christiania telephone line prove a success, a Christiania-Gothenburg line will probably, ere long, be taken in hand. The work in connection with the Swedish-Danish telephone, under the Sound, is also in full swing. The new line between Malmö and Hildesborg, on the Swedish coast, is about completed; and the Copenhagen-Vedbök line, on the Danish side is also in hand. There will be double wires on both sides. One of the existing submarine cables will be used. Conversations between Denmark and Sweden will be limited to three minutes, and the charge for a conversation with Malmö and surrounding district will be eighteenpence, which cannot be considered an excessive charge; for more distant parts of Sweden the charges will be higher. The Swedish State telephones are going ahead at a great rate, and in spite of the youth of this institution it has entirely put the State telegraphs in the shade as far as cost of installation goes. Another million of krone was not long ago placed at the disposal of the State telephones, which will be applied to the purchase of private telephone companies, and to the erection of a new central station at Gothenburg.

The Electrical Transmission of Power.—In the Foreign Abstracts published by the Institution of Civil Engineers there is a reprint of a Paper read by M. E Hartmann before the German Society of Engineers, in which details are given of the efficiency and working cost of power electrically transmitted to working machine tools, lifts, and cranes. When the works of the General Electrical Company, of Berlin, were designed, provision was made to distribute power through the various departments electrically. The system adopted consisted in grouping machine tools so as to receive power from short lengths of light main shaftings, each length of shaft being worked by an electromotor. In some special cases each machine was provided with its own motor. In all there are now some forty motors in use, with a total of 400 H.P., which is distributed by cables from a central station in the works. Experiments were made to ascertain the total efficiency of power transmission between the central steam engine and the various machine tools, the latter working under ordinary conditions; and it was found that about 64 per cent. of the power developed was actually delivered to the various machines. Herr Hartmann also made tests in another factory where long lines of heavy main-shafting transmitted about 250 H.P., and found that the efficiency under normal conditions of working was only 54 per cent. A further set of experiments concerned the efficiency of helical spur-gear (97 per cent.) and worm gear (84·6 per cent.). An example is given where the substitution of electricity for mechanical transmission resulted in considerable saving of power. This was a grist mill originally driven by shafting giving an efficiency of 51 per cent. After the introduction of the electric plant the efficiency rose to 74 per cent. The author next compares electric transmission with the employments of small steam engines, scattered about in various shops, and receiving steam through long steam pipes. He finds that under these circumstances not less than 48lb. of coal are consumed per horse-power hour, whereas with electric transmission the consumption is reduced to 24lb.; and he cites as an example the railway works in Görlitz, where 100 H.P. is so transmitted. He next considers the electric transmission of power to lifts and cranes, and compares it with pneumatic and hydraulic transmission, finding that in most cases the electrical system is more efficient.

REVIEWS.

Electrical Papers. By OLIVER HEAVISIDE, F.R.S. 2 Vols., pp. 560 and 578. (London: Macmillan and Co.)

These volumes consist principally of reprints of Papers published in *The Electrician*, and in the *Philosophical Magazine*, and other papers at various dates since 1872 and up to 1892. In the Preface Mr. Heaviside ventures on a most unnecessary apology for publishing them. They are much too valuable scientifically, practically, and historically to be left buried discontinuously in a variety of serials. The Editors of *The Electrician* are to be most particularly commended for their public spirit in publishing such long series of Papers which can only have been interesting to a small minority of their readers, but which were so principally because the Papers were pioneers in the subject they treated of.

The Papers are valuable scientifically because they contain a consistent and sound method of attacking electromagnetic problems in consonance with, and in extension of, Maxwell's theory, and because they contain very valuable scientific results deduced by this method from this theory. The Papers are valuable practically because they teach a sound theory of telegraphs and telephones, and of other matters, such as induction balances, which has already resulted in Prof. S. P. Thompson's patent for increasing induction in telegraph wires, and which, there is every prospect, may lead to vast improvements in telegraphy and telephony, and may even make it possible to work a telephone across the Atlantic. The Papers are valuable historically as being a most interesting record of the development, methods, and scientific views of nature, in an extraordinarily acute and brilliant mind.

Many complain that Browning is unintelligible. Some say that he writes nonsense. His admirers worship him. Oliver Heaviside has the faults of extreme condensation of thought and a peculiar facility for coining technical terms and expressions that are extremely puzzling to a reader of his Papers. So much so, that there seems very little hope that he will ever attain the clarity of some writers, and write a work that will be easy to read. In his most deliberate attempts at being elementary, he jumps deep double fences and introduces short-cut expressions that are woeful stumbling-blocks to the slow-paced mind of the average man, when reasoning about concepts that he (the average man) is not very familiar with. Combined with this is a delightful freshness of illustration and brusqueness of expression that makes some parts of his Papers very lively reading indeed. For example, in connection with the nature of matter he says, "Even if we resolve all matter into one kind, that kind will need explaining. And so on, for ever and ever deeper down into the pit at whose bottom truth lies, without ever reaching it. For the pit is bottomless." These personal characteristics of style increase very much the historical value of this reprint. It is this historical value that compensates very largely for the considerable amount of repetition which makes the work longer than a connected new work on the subjects included in the Papers would be. The repetition is largely due to the way in which the Papers were published in various serials and in several series. In each, much preliminary ground had to be gone over in order to make the succeeding extensions intelligible to those who might not have seen the preceding series. Repetition in a minor degree arises from the development of method that was proceeding in the author's mind and that required former results to be reviewed in the light of improved methods and advanced results.

It will be convenient to divide the consideration of these Papers into remarks on the author's methods, on the theories he has developed, on the practical applications of these theories, and on the innumerable questions as to the nature of things which he raises.

The great advance in method that the author has made is due to his consistently following out the principles that Maxwell laid down in accordance with Faraday's ideas as to the nature of electromagnetic actions. Maxwell had clearly pointed out that the state of the ether at each point depended upon the electric and magnetic forces there, and upon the electric and magnetic diplacements they produced. Maxwell, like every other poineer who does not live to explore the country he opened out, had not had time to investigate the most direct means of access to the country nor the most systematic way of exploring it. This has been reserved for Oliver Heaviside to do. Maxwell's treatise is cumbered with the *débris* of his brilliant lines of assault, of his entrenched camps, of his battles. Oliver Heaviside has cleared these away, has opened up a direct route, has made a broad road, and has explored a considerable tract of country. The maze of symbols, electric and magnetic potential, vector potential, electric force, current, displacement, magnetic force and induction, have been practically reduced to two, electric and magnetic force. Other quantities it may be convenient, for the sake of calculation, to introduce, but they tell us but little of the mechanism of electromagnetism. The duality of electricity and magnetism was an old and familiar fact. The inverse square law applied to both, every problem in one had its counterpart in the other. Oliver Heaviside had extended this to the whole of electromagnetics. By the assumption of the possibility of magnetic conduction he has made all the equations symmetrical. Every mathematician can appreciate the value and beauty of this. Can anyone be sure that the ether does not ultimately yield to magnetic force? Can we be sure that there is absolutely nothing corresponding to that diffusion of strain that exists in almost every solid? Can we assert positively that there is no diffusion of motion, such as Lord Kelvin has pointed out interferes seriously with vortex hypotheses as to the structure of the ether?

In addition to this he has done his best to popularise vector analysis. For what, to those familiar with Hamilton's notation, seem very insufficient reasons, he has sacrificed a great deal of what was valuable in Hamilton's methods. In order to avoid a negative sign and the occasional use of S, he has given up the versor interpretation of his symbols. He was driven to this apparently by the semi-metaphysical foundation upon which Hamilton based his system, which, however, can be based upon a series of definitions just as easily as Mr. Heaviside's own system. That one who works with sin, cos, tan, cotan, sec, cosec, sin$h$, cos$h$, tan$h$, cotan$h$, sec$h$, cosec$h$, $I_0(ix)$'s, &c., &c., should be troubled by an S and a – sign seems too incredible for this latter reason to have really influenced him; but there is no difficulty in understanding how one who is so constantly requiring to see clearly how his symbols represent the facts should have been deterred by a semi-metaphysical basis from resting on another man's foundation, and should have invented a system for himself with a foundation that he clearly understood.

Running through a good deal of his work and coming to a definite suggestion in the last volume is the question of units of measurement. That eternal 4π troubled him as it has troubled everybody else. It is nearly true that the only rule for introducing it is to consider carefully whether it should be in or no, and having come to the conclusion that it should not be in, then immediately introduce it. It is to be regretted that we inherit the misfortunes of our ancestors, and that electrical and magnetic phenomena were known before electromagnetic ones, and that thus the 4π came in so unfortunately, but there is too much capital sunk in the present system for it to have any chance of changing. When people tolerate miles and furlongs and pecks and bushels and barrels and firkins and hogsheads, &c., &c., how can they be expected to get up any enthusiasm over the eviction of 4π?

In the theory of electromagnetic phenomena the author has made great advances. He has extended the theory of wave propagation in complicated media, of waves along wires and into them, and of the effect of the motion of the medium. The questions are too scientifically technical to enter into here, but it must not be concluded that because they are only shortly noticed that therefore they are unimportant. In fact the extension he has given to the theory of the propagation of waves outside and inside telegraph wires is the foundation for

Digitized by Google

a large part of the most important practical applications of electromagnetic theory that he has pointed out.

The most important practical applications of his theory are to the use of induction balances and to the improvement of telegraph and telephone lines. In this latter field he is unique as an investigator, and everyone of his suggestions is worthy of the most serious consideration by those who desire to advance this application of electromagnetic energy. In this connection he has called particular attention to and worked out in a very complete manner the penetration of the current into the conducting wire, the effect of the self-induction in neutralising the evil effects of capacity, the effect of leakage in improving signals, and the conditions that the terminal receiving instruments must fulfil in order that they may not themselves introduce confusion. The effects of all of these, except leakage, are now quite familiar to users of alternating currents, thanks in no inconsiderable degree to Mr. Heaviside. Long before tube conductors were used on the Deptford installation this theory was worked out by him and equations given for calculating how thick the tubes should be which should have been usable by properly educated practical electrical engineers, or which should at least have shown them that Mr. Heaviside was the person whom they should consult upon such a point. Long before Mr. Ferranti observed a, to him, new rise of voltage in London, Mr. Heaviside had called attention to the same thing in connection with telegraph signals, and had shown to what it was due and on what principles it could be avoided, by the use of carefully designed receiving instruments. Long before practical engineers were at all familiar with the way in which capacity and self-induction produce opposite effects upon the difference of phase between volts and amperes, Mr. Heaviside had shown how to use this in designing telegraph cables in which some of the evil effects of capacity could be to a large extent neutralised by increasing the self-induction. Before Prof. S. P. Thompson took out patents for increasing this self-induction, Mr. Heaviside had suggested and had proved the efficiency of putting iron filings into the insulation of a cable, had suggested drawing a double wire of iron and copper, and had shown that by winding iron wire like gimp outside the copper wire a continuous self-induction might be obtained which would improve the efficiency of telegraph and telephone lines. Everyone is familiar with the way in which self-induction alters the impedance more and more the greater the frequency. What Mr. Heaviside has shown is that by a proper combination of self-induction and capacity the effects on waves of small frequency can be made nearly the same as on those of large frequency, and that consequently speech, which consists of a mixture of waves of all sorts of frequencies, can be much better transmitted than by a line in which either capacity or self-induction preponderates. He has further shown that by a proper regulation of leakage it is possible to still further improve articulation. Telephony, in accordance with Mr. Heaviside's predictions, has advanced so much of recent years beyond what was a few years ago regarded as its limits, that it confessedly requires an amended theory. When the properties of a line have to be determined experimentally after it has been laid down, it is confessed that the theory of those who are unable to predict its behaviour is incomplete. Mr. Heaviside is, by the practically unanimous opinion of scientific experts, and by his success as a prophet, pointed out as the authority from whom this amended theory comes, and who should be consulted by all those who desire to improve telegraphic signalling. He is a scientific expert of the best kind in these subjects, and it is very much to be regretted that scientific experts are, in these countries, so highly paid to advance causes and so very seldom paid to advance practice. The telegraph department has, however, shown itself anxious to improve the means of communication by applications of the most recent scientific ideas, and it is inconceivable that any personal friction should really stand in the way of the utilisation of what the Royal Society has crowned with a Fellowship.

The questions of scientific and practical interest raised by Mr. Heaviside are innumerable and most suggestive, as might be surmised from the acute and ingenious nature of his intellect. He has traversed the Von Helmholtz theory of a double electrical layer at the contact of dissimilar bodies, and Clausin's theory as to the Thomson effect being due to change of structure. This latter is largely a question of words and of the meaning of the term "change of structure," and the author's theory as to the former is surrounded by serious difficulties, as, indeed, is every theory as to the connection of matter and electricity. There are discussions as to the internal energy of a magnet which are interesting in connection with the puzzle as to why the self-induction of a circuit is independent of the magnetic field. He raises questions as to the equilibrium of the ether when transmitting radiations owing to the pressure exerted by alternating currents upon conductors, as to the flow of energy through the ether, as to magnetic storms and earth currents being connected with solar waves, as to the rate of subsidence of earth currents, as to the behaviour of metals to light, as to the nature of lightning flashes, as to the effect of the motion of matter through the ether, as to the inertia of electric currents, and as to many other matters. As regards solar waves causing earth currents, Lord Kelvin has pointed out a serious difficulty in the enormous amount of energy that such a radiation would require, from which it would seem that if magnetic storms are due to solar causes they must be connected either very indirectly with solar magnetic storms, or else that the electromagnetic influence is confined to some ray projected from the sun, and which happens to cross the earth; though, here again, it is difficult to see how such a ray can be produced unless it is a projection of electrical ions in some of the outlying streamers of the corona. In connection with this matter of electromagnetic waves, it is interesting to observe that any moving body magnetised like the earth is continually emitting waves and losing some energy, though, in the case of the earth, an almost infinitesimal quantity. It would be interest to consider the problem of the motion of two oppositely electrified bodies round one another. The question would be complicated by the finite rate of propagation of the influence between them, and by the loss of their energy by radiation. In view of the Maxwell light pressure, would moment of momentum be conserved? or would the problem be practically the earth-moon problem with tides absorbing energy? How would the aberration of the force due to the velocity of the bodies and of the force affect the problem? In connection with the question of the inertia of electric currents we owe it principally to Mr. Heaviside that he has put away the temporary function that Maxwell introduced as the inertia of the current, and has concentrated attention on the magnetic force as the true source of what is analogous to inertia in electromagnetic questions. In view of the duplex nature of electromagnetic phenomena, which Mr. Heaviside more than anybody else has taught us to recognise, it is a little startling to find him stating so very confidently that electric current has *no* inertia, while it would appear from this very duplex property that we might *à priori* have attributed *all* the inertia to the electric force and none to the magnetic, just as satisfactorily as the reverse. It is evident, however, that we must know more about the structure of the ether, and possibly of its connection with matter before we can finally decide what is the really soundest view of the matter, and that no finally satisfactory answer will be given until all energy has been explained as kinetic energy.

Since Oliver Heaviside has written, the whole subject of electromagnetism has been remodelled by his work. No future introduction to the subject will be at all final that does not attack the problem from at least a somewhat similar standpoint to the one he puts forward. It is to be hoped that some author with a genius for popular exposition will soon write a "New Electromagnetism" with action at a distance strictly tabooed. With electric pressure and the displacement it produces as the source of the electric energy per unit volume in the ether, and with magnetic momentum and its accompanying flow as the source of the magnetic energy per unit volume in the ether, with these as the leading ideas of the work. Such a work would be electromagnetism up to date, and its possibility would be largely due to Oliver Heaviside.

POSSIBLE AND IMPOSSIBLE ECONOMIES IN THE UTILISATION OF ENERGY.*

BY PROF. ALEX. B. W. KENNEDY.

(*Continued from page 365.*)

It is certain that no steam engine in existence works in a ycle which would give out—even if the cycle were perfectly ırried out—this efficiency. But it is also certain that we can- ɔt, by any changes or inventions whatever, make any engine ork in a cycle which shall have a higher efficiency. So, for ıch general purposes as the present, it is quite sufficient to ok upon it as a maximum value, and a limiting value, and limiting value which falls tolerably short of unity.

I am, not, of course, able here to give you my authority, or) reason out the statements I have just been making. I ust only ask you to accept my statement that in attempting transform heat energy into mechanical energy in any ıysically conceivable steam engine, we start with an absolute ıpossibility of getting more than 30 per cent., or so, of the

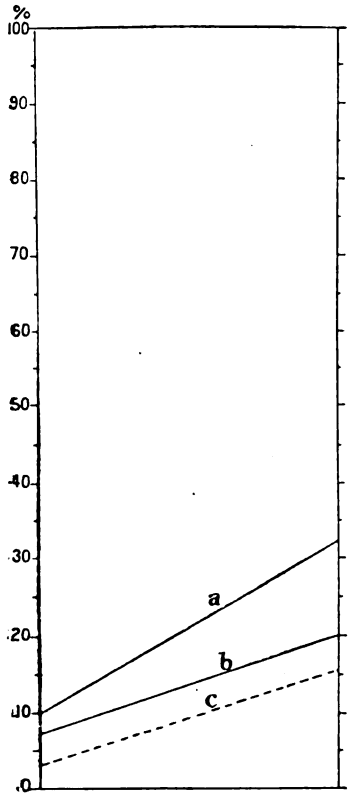

Fig. 4.

ɔrmer to appear as the latter. That is to say, our richest con- eivable ore might contain 30 per cent. of metal. What we ıave actually to do, however, is to work with far purer ores han this. In any actually possible steam engine the process liffers so much from the ideal that not more than 20 or 25 ɔer cent. could be attained even if the process were carried ɔut perfectly. But there are very great difficulties in the way ɔf carrying out even this imperfect process at all completely, ınd so it comes about that, in the final results, only from 5 to ɔerhaps 15 per cent. of the whole heat of the steam is ever urned into work, sometimes a little more, more often a little ess.

Ninety per cent. of energy wasted, to say nothing of 95 per ent., seems to leave a glorious field for improvement. It ooks so much as if, somehow, we ought to be able to do ten imes, or twenty times, as well as we are doing, with such a remendous margin of possibilities.

I may illustrate the real state of the case by Figs. 4 and 5. In Fig. 4 100 per cent. is taken as representing the whole heat of the steam. The area under the line *a* represents the proportion of this which might actually be turned into work with an ideally perfect engine, working in an ideally perfect cycle. The area under *b* represents the amount which might be turned into work by an ideally perfect engine, working in its actual cycle. Lastly, the area under *c* represents the total amount of energy which actual engines do turn into work. In each case the left-hand side of the diagram represents a poor machine, and the right-hand side a good one. In Fig. 5 I have taken the ordinates of the line *a*, as representing 100 per cent., and drawn the other two below them in their proper relative places. This is equivalent to saying that we cannot increase the richness of the ore, and that we give up any attempt to utilise the large spaces shown above *a* in Fig. 4, for the simple reason that it is impossible to do so. Fig. 5 therefore shows what really is possible. It will be seen that the margin is large enough, but the possibility is only of doing twice, and not ten times, as well as at present. It is sad to think how much time and thought has been spent in kicking against brick walls in this matter. Nature, however, is inexorable, and will not allow us to pretend that larger savings are possible than she

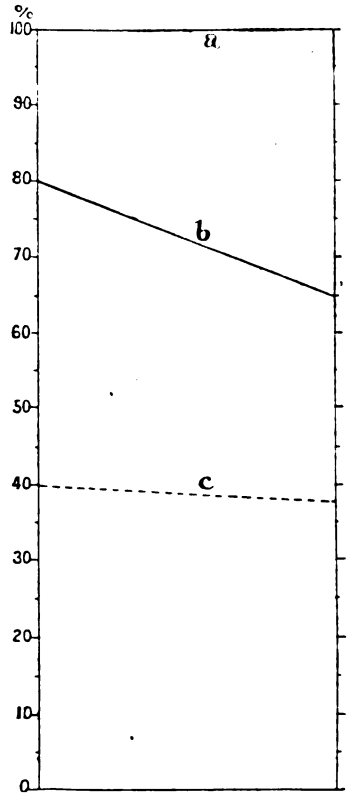

Fig. 5.

will allow us. But while I put things strongly in this way, do not let me be supposed to suggest that nothing can be done to diminish the huge proportion of waste energy indicated by Fig. 5.

Looking back again at Fig. 3, what possibilities are there of increasing the theoretical maximum efficiency of an engine? The whole matter depends upon whether we can increase the value of the fraction $\frac{T_1 - T_2}{T_1}$; practically that is all. We can do this obviously by either making T_1 higher or T_2 lower, or both, but without doing one or the other I will ask you clearly to remember that the huge waste area in Fig. 4 is absolutely inaccessible to us. It is not difficult to see how this matter comes out practically. In all heat engines some fluid or other is used as a vehicle for the transformation of heat into work. It may be coal gas or producer gas, steam, air alone, or air mixed with the products of combustion, or even ether or ammonia. With steam we work between the temperatures of, say, 60° or 400° F., or thereabouts. Quite at the other end of the scale come engines worked by gas of different kinds, where

* Lecture given at the Royal Institution, April 21, 1893.

Digitized by Google

combustion actually take place inside the engine and not in a furnace, and where the highest temperature may, perhaps, be as great as 2,000° F. Hot air occupies an intermediate position with ether or ammonia; the temperatures are all very much similar. From our present point of view it is necessary to remember that all these divers working fluids work under the same physical laws and limitations. There is no dodging of thermodynamic principles possible. Nature, in fact, cannot be persuaded, even by the most seductively worded prospectus, to make exceptions in favour of particular materials. How, then, do these various working fluids stand in reference to this problem of economy?

First of all, the mere nature of no one gives it any advantage whatever. The fact that steam can be liquefied in a condenser is a great convenience to us, but does not make it, *per se*, one whit worse or better than air, which cannot be liquefied, at least in a condenser. The manner in which the choice of fluid affects the value of the maximum possible thermo-dynamic efficiency is indicated in Fig. 6, which may be taken really as a diagram—to use our former illustration—of the richness of ores. With gas, the highest temperature is the temperature of combustion; the theoretical maximum efficiency is so very high that we might look upon the gas as being almost a nugget. With air, the temperature is only indirectly

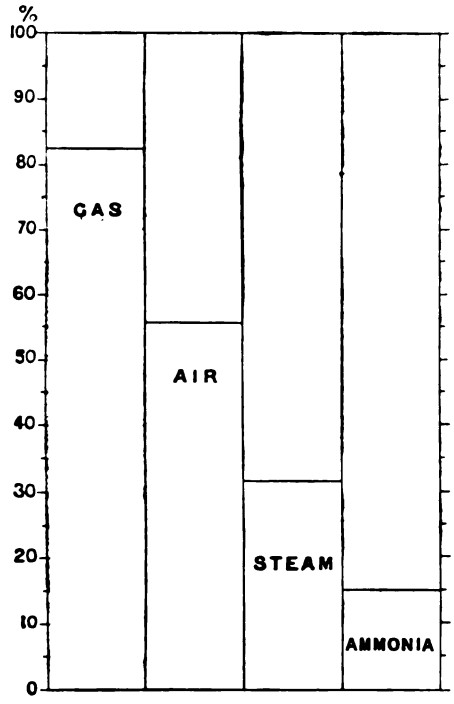

FIG. 6

derived from the temperature of combustion, and the maximum efficiency is smaller, although it is still high. With steam (apart from super-heating) the temperature is dependent upon, and limited by, considerations of pressure, and consequently of safety. With ammonia it is similarly limited; but the engine lies much further down the scale, both as to T_1 and as to T_2.

From Fig. 6 we may gather that with gas engines the theoretical efficiency is already so high that we need hardly trouble ourselves about attempting to raise it. With gas, in fact, and to a smaller extent with air, the possibility of improvement lies in bringing the actual up to the theoretical process, and not in attempting to raise the efficiency of the latter; that is to say, we must with them leave the losses represented by Fig. 4 alone, and try to deal only with those shown in Fig. 5. With steam, however, it is different. We want much to raise the theoretical limit of efficiency. But here we are dealing with a material which is liquid at ordinary temperatures and pressures, so that in its working condition it is a vapour and not a gas, and its temperature cannot be raised without at the same time raising its pressure. Considerations of safety and strength of our materials become here very important, but even if we left them out of account altogether, and raised the value of the maximum working pressure of steam engines from its present limit of 10 atmospheres to 20 atmospheres—that is, 100 per cent.—we should have increased the theoretical maximum efficiency only about 10 per cent., a quantity hardly worth considering in such a case. Clearly this is not a very promising direction in which to work.

No doubt the direction in which to seek for improvement is in that of what is called super-heating the steam, or raising its temperature after it has been formed—converting the vapour into gas without increasing its pressure. Theoretically this can be done to any extent, and I have no doubt that within the next coming years it will be very largely done. It is no new idea, although it is only recently that the use of mineral lubricants in engines has made it thoroughly practicable. As an illustration of its great benefit, I may mention that I found, some two years ago, that a little ordinary 4 H.P. engine, one cylinder, late cut off, moderate pressure, worked by a Serpollet boiler in which the steam was super-heated 200°F., gave results positively much better than I obtained not long after from a fine 100 H.P. Corliss engine, made by one of the best firms in Lancashire, and used in the ordinary fashion, with the same steam pressure but no super-heating.

Under ordinary circumstances I should have expected the little engine to use at least four times as much steam per horse-power hour as the large one.

At one time, when high-pressures were looked at askance and high-temperatures were thought almost as impossible, great hopes were entertained of increasing efficiency rather at the bottom than at the top end of the temperature scale. It was proposed to use an auxiliary engine working with ether or anhydrous ammonia, or any other substance whose boiling point might be made as low as the temperature in the condenser of the steam engine. But there are such great practical objections to this plan that it has at present disappeared from the range of practical engineering. Undoubtedly, the most promising direction for improvement is to go up, and not down the temperature scale, and he will be a great benefactor to us all who will devise a good and not too bulky super-heater applicable readily to existing work.

All this is rather in the direction of potential than of actual improvement, viz., improvement in Fig. 4 rather than in Fig. 5. In the latter, however, there are still large possibilities, as the Figure shows. The losses here are due to many causes, but chiefly to two. The first of these is that the steam is thrown away at too high a pressure, *i.e.*, that it is not expanded sufficiently far in the cylinder. Mechanically this is remediable at once, but only at the cost of making the engine unduly large and costly for its work. This cause of loss is, therefore, likely to remain. The second is one about which there has been much controversy both here and abroad, but which, thanks to the work of such men as Willans and Cotterill and Donkin, is now much cleared up. It is simply this—that as the fresh hot steam is always admitted to a cylinder which has just been emptied of steam having a much lower temperature, a cylinder, moreover, which is made of excellently conducting material, a very large proportion of that steam is at once converted into water on entrance, so that for every cubic foot of steam which leaves the boiler and passes along the pipes perhaps only two-thirds, or even half or less, does work in the cylinder as steam; the rest passes through the engine as water, or is sometimes partially re-evaporated, but never in such fashion or at such time as to be of much real service in doing work. There are thousands of engines at work to-day in which for every ton of water which has been evaporated in the boiler half a ton does no good whatever, except to warm up (by being condensed itself) the engine sufficiently to allow the other half ton to do work.

Here truly is a field for economy, and one with very great possibilities. I do not speak here of steam jacketing and other methods in partial mitigation of the waste, for these could hardly be discussed except in a very technical fashion. I will only say that there is no doubt that the great benefits which have been derived from super-heating, and the still greater possibilities of economy which exist in it and will probably soon be more heard of, are not at all only connected

Digitized by Google

with the rise of maximum theoretical efficiency. The drying of the steam very largely influences its behaviour under the conditions I have mentioned, and unquestionably helps enormously to diminish the waste area in both Figs. 3 and 4.

I have talked long about steam engines. The subject is tempting, at least tempting to me, and, after all, steam is still the working fluid *par excellence*. But I must not forget that my subject has many branches, and must look at some of the others.

I say nothing about hydraulic motors, as the subject is one in which I have practically done no work, and I do not wish to give you second-hand figures.

The future of gas engines is one which has great possibilities; we have seen that they represent, in fact, the richest ores which we have yet discovered. Up to a certain point their progress was astonishingly rapid; at present, for a few years, it has more or less stood still, although the number of them has continually multiplied. Just now there are signs that the manufacturers—just possibly it may have something to do with the pressure of severe competition—are going to do their best to move forward a little, to make larger and faster running machines, and, in fact, to make an effort to penetrate further into the country where the steam engine has for so long held undisputed sway. About this we must not concern ourselves here, however. In Figs. 7 and 8 I have put down in a diagram the present state of gas-engine working, so far as I have been able to analyse the results of some of my own experiments. These figures are arranged to correspond with Figs. 4 and 5 for steam engines. In Fig. 7 the maximum theoretical efficiency is seen to lie about 80 per cent., as represented by the line *a*, the heat actually turned into work is represented by *b*. It is obvious that our theoretical maximum efficiency is so high that we need hardly attempt to raise it, especially as we are so far from actually realising it as yet. In Fig. 8 the theoretical maximum efficiency is taken as 100 per cent., and the line *b* shows how much of this is actually turned into work, the area above *b* representing the lost energy. The greatest cause of loss, that above the line *c*, is represented by the heat taken from the water surrounding the cylinder. The fact is we are trying to obtain incompatible results. To reach the high efficiency we make the initial temperature very high.

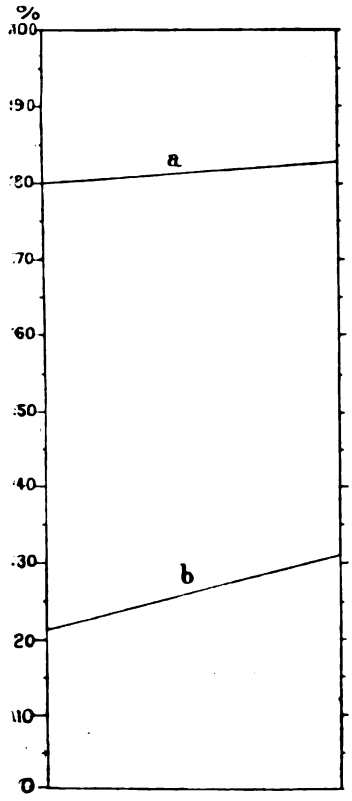

Fig. 7.

But, then, any such temperature would melt up our machines altogether, and leave it as flat as Ice Peter in the picture book after he had been put against the stove, if the metal were only allowed to reach it. We have, therefore, to adopt the somewhat barbarous expedient of continually keeping the metal cool by a current of water passing through a jacket. This water must of necessity pick up all the heat which can get through the metal and carry it away to waste. The result is obvious in the figures. Although, therefore, our theoretical maximum efficiency is so much greater than that of a steam engine (comparing the lines *a* in Figs. 4 and 7), our actual efficiency is not nearly so great (comparing the lines *b* in Figs. 5 and 8). Notwithstanding this, the actual energy utilised per thermal unit of combustion heat in a gas engine is very considerably greater than in a steam engine.

Undoubtedly, very great possibilities for increased economies exist here. The appearance of a new type of gas engine which should use only half the gas per horse-power hour which present engines used, would doubtless be received with scepticism, but with all that one could not say for certain beforehand that it was an absolute fraud, and I am quite prepared to hope that it may make its first appearance presently. But it is not at all so easy as in the case of a steam engine to suggest the direction in which to work for increased economy. Paradoxical as it may seem, it is not improbable that a *reduction* of the initial temperature might in this case be attended with economy; there is no doubt some one temperature at which the loss and gain just mentioned would adjust themselves most advantageously. A solution of the whole matter—a solution which would also greatly help the steam engine problem—would be the discovery of some non-conducting material which was at the same time suitable for use in the construction of engines. Chemists have done much for us, but we still wait for our non-conductor! Something as strong as iron and as easily machined, with the conductivity of sawdust, is what we want, a material which at the same time must remain sensibly unaffected by excessively high temperatures and which will stand rubbing to any extent. Perhaps the coming man, who is to produce this stuff, is here to-night. If so, I congratulate him on his future.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Paley, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; and Sir James Anderson, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

LOGIC AND ENGINEERING.

Of all the exact sciences, formal logic is the one which receives from practical engineers an amount of attention which is least in proportion to its intrinsic merit. Yet it is one, of which it is only necessary to state its scope and meaning, in order to completely demonstrate it great importance, alike to the practical man as to the theorist. The science of exact reason is, in fact, the essence of all the reason in exact science; and, apart from it, there can be neither reliable practice nor accurate theory. Whether, on its deductive side, the inferences from established principles in science have to be drawn in relation to some special problem; or whether, on its inductive side, it is necessary to arrive at the generalised truth which underlies and co-ordinates any given set of special facts, the processes by which science, and engineering science in particular, must extend into new fields or strengthen its hold on fields already taken, are founded strictly upon the abstract laws of logical thought. Whether, for example, the theorist seeks to find out the essential principle which underlies the known series of electromagnetic and optical phenomena, and thus to arrive at—inductively—some exact knowledge of the ether; or whether the practical engineer wishes to locate a "fault" in his system of cables, or "knocking" in his steam-engine; it must ever be by a more or less exact, or more or less crude and unconscious, application of logic. This being the case, it would seem that very little argument ought to be necessary in order to establish the science of exact reason as a regular branch of scientific training. Unfortunately, however, there are so many specious objections raised against this practice that it will require a much

Digitized by Google

more vigorous effort in favour of logic before it is likely to be accepted very generally.

One of the most common objections is, that formal logic is unnecessary as a *separate* training, since it is implied in all the other exact sciences which are taught; that in other words, mathematics, theoretical physics, chemistry and mechanics, and the free use of laboratories, are enough to render a student logical. To such objection there may be granted this much; that the systematic and proper study of the sciences named does, in time, induce a logical form of mind, and trains the student's mind to run in proper grooves instead of flitting about like a butterfly. But the result is by no means as rapid or as satisfactory as would be the case if the sciences we have named were preceeded by a short and practical course of logic. Before being told *what* to think the budding engineer should be shown *how* to think. This is more particularly necessary on account of the far from perfect way in which science is taught in many of our schools and colleges. Arithmetic is dealt with as if it were a set of conjuring tricks, the main object of which was to find out the price of eggs a dozen when a certain number turn out to be bad. Chemistry is the science of juvenile fireworks. Mechanics is a dodge for remembering several "systems" of pulleys, "orders" of levers, and the "five mechanical powers or simple machines," to say nothing of the first, second and third laws of Newton, the "laws" of thermodynamics, and of falling bodies. Mathematics is either overladen with formulæ, which obscure a principle instead of elucidating it, with problems which harden the mind in tricks, or with graphic methods which are remembered rather than understood. There is, in short, a general obscuration of fundamental principles under a dazzling show of phenomena or a puzzling array of problems. Pure mathematics, in its purity, is, of course, nothing less or more than formal logic; and it is for this reason alone that the study of EUCLID'S geometry exercises so healthy an effect on the youthful mind. It is greatly to be regretted that a falsely utilitarian tendency exists in some quarters to oust euclid, and replace it by more modern geometry; for this more modern thing, although more in touch with practice, is far less directly and convincingly logical.

But even were the other sciences taught in an ideal manner, there would still be a strong argument for logic as a part of an engineer's training. The fact that the sciences we have named are isolated from engineering, and taught previously to it, is, indeed, the very reason why logic, too, should be isolated and separately taught. If logic is so integral a part of every science which is the basis of engineering, it should on that account receive due consideration; which it can only receive by separate attention. If, for example, it were proposed to abolish the practice of teaching pure mathematics, leaving the student to pick up his mathematics as he went along with his physics and mechanics, the outcry would be loud and convincing. Yet logic is only an extension to concrete thought of the processes of abstract thought implied in pure mathematics. Logic does for the world of ideas about machines and energy what mathematics does for the abstract world of space and number.

Another objection which is often opposed to the teaching of logic in schools and technical colleges is that it is "dry," uninteresting and abstruse in the highest degree. In the first place, this is not a valid objection, because students do not go to class to be amused. In the second place, there is no reason why logic, any more than trigonometry, should be dry and uninteresting, and the elements of logic are not abstruse. Many of the systems of logic, especially those which follow BOOLE in his attempt to establish a system of logical calculus by means of which one might think by signs and wonderful formulæ, are certainly both uninteresting (except historically) and unnecessary. But the most important branches of logic—the logic of fallacies, of dilemmas, and of probabilities—are capable of even a fascinating treatment. The well-known "Adventures of Sherlock Holmes" is an admirable text-book on these branches of logic, and is even recognised as such in more than one medical college in this country. It is sometimes said that every really practical man, however badly educated, has an instinctive form of logic which prevents blunders or quickly remedies them,—a sort of habit, founded on experience, the reasons for which the man is generally quite ignorant of. His conduct is logical but his logic is unconscious. This is undoubtedly often, though not always the case. Where it is the case, the intuitive faculty would receive valuable assistance and development from education, as every intuitive faculty would do. Where it is not the case, education will generally train into activity a latent power, or will implant an absent one. In every case, direct education along scientific lines must enormously increase the probabilities of correct thought and sound judgment.

The difference between a logical and an illogical engineer is all the difference between the man who can forsee a breakdown or a mishap and avoids it, and the man who goes bungling headlong into it, making "confusion worse confounded" by his ridiculous attempts to clear himself. It is the difference between the man who can adapt himself readily to altered conditions, and the man who goes on in the same old-fashioned, hum-drum, rule-of-thumb manner wherever he may be. It is the difference between progress and retrogression; between a successful engineer and one who finds life a failure.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 368.)

It was stated in the chapter on "Mounting," that a heavy deposit is produced more quickly under a liquid than in a gas. For this reason it is best to flash in a gas, at any rate in the case of small-current filaments, as a thick deposit is not required. As a matter of fact, the deposition of carbon always takes place from the gas, even when done under the surface of a liquid. The liquid in contact with the filament is intensely heated, and by the time the filament is red hot the liquid round it is boiling so violently that the vapour alone comes into contact with it. It is this vapour which is decomposed and produces the deposit on the filament. There is produced in this way a hydrocarbon vapour of great density surrounding the filament, and hence the rapid deposition of carbon. In reducing the resistance of a filament by flashing, it is necessary that the process be not too rapid, or a slight error in stopping the current at the right moment will considerably overstep the mark. For thin and high-resistance filaments, such as for 100-volt, 16-c.p., or 8-c.p. lamps, the process must be made much slower than for filaments for lamps which will take several amperes of current. It is consequently easier to flash low-current filaments successfully in a gas than under a liquid, and the gas may further be considerably rarefied.

Ordinary illuminating gas can be used for flashing in at atmospheric pressure. In this case the apparatus required is very simple, as shown in Fig. 11. A is a glass bell jar ground flat on the top and bottom, so that with the aid of a little grease it stands gas-tight on the brass base-plate B. Through this plate pass the tubes C and D, one being the gas supply and the other the exhaust pipe. E is a plate made of hard

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of re-publication reserved.

Digitized by Google

wood, which carries two spring clips, G G, for holding the filament H. On the upper side of this plate are two metal contact plates, F F, connected with G G, the whole of this arrangement being removable. A spring contact arrangement, K, makes the electrical connection with F F, and at the same time holds the plate E firmly upon the top of the bell jar so that it is gas-tight. To work the apparatus, a filament is put into the clips which are then inserted in the jar, and the spring contacts are let down on the top. Gas is then turned on through G, and air and gas escape through D. In a short time there will be very little air left in the jar, and the current may be turned on and gradually increased by means of a regulating resistance, until the filament is brightly lighted up. The deposition of carbon now begins, and the resistance of the filament becomes lower and it gets much brighter. This, perhaps, at first sight appears curious, as it will be remembered that when depositing on a joint the joint became dull. Whether the filament or joint becomes brighter or duller as the deposition proceeds, simply depends on the amount of resistance in series with it. In starting a high-resistance filament it probably requires all or nearly all the available electrical pressure to light it up, and consequently the regulating resistance is mostly if not all cut out. As the resistance of the filament decreases the current increases, while

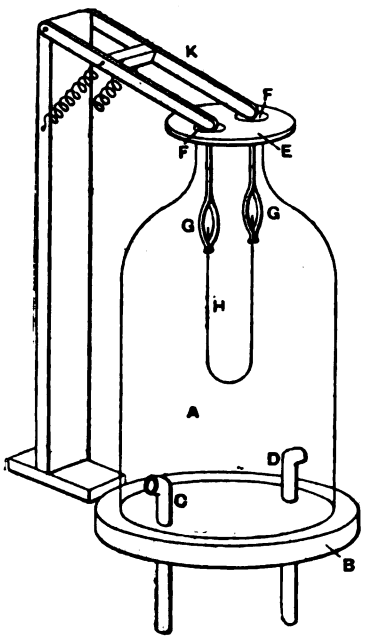

FIG. 11.

the volts remain the same, or nearly so. The filament consequently becomes brighter, and the temperature must be kept down by adding resistance. On the other hand, if, when the filament is lighted up, there is a resistance in circuit greater than the resistance of the filament, it will become duller as the deposition proceeds, for, though the current through it will be greater than at first, the difference of potential at the ends of the filament will be less in a greater ratio, and there is consequently less power being expended in it. Some of the regulating resistance must consequently be cut out to keep the filament bright. The total E.M.F. used should be just sufficient to light the filament up to the required brightness for the deposition, without any extra resistance in the circuit. As the deposition proceeds and the resistance of the filament falls, resistance must be added to the circuit in order to keep the temperature of the filament constant. More and more resistance has thus to be added until the added resistance is equal to one-fourth of the resistance of the filament when first lighted up. When this point is reached the resistance of the filament itself will also be one quarter of its original resistance. If the deposition is continued beyond this point, the added resistance is gradually cut out of the circuit again, as the filament henceforth gets duller instead of brighter as its resistance continues to fall. It is here assumed that the total E.M.F. is kept constant and that the same number of watts are expended in the filament throughout the process in order to maintain it at the constant temperature. As a matter of fact more power is required as the process proceeds, owing to the increase in thickness of the filament, so that the greatest amount of extra resistance required will not be so much as one-fourth of the original resistance of the filament. It is not often that filaments are flashed to the extent of reducing their resistance to one-fourth of the initial value.

The filament must, therefore, be kept at the required brightness by the variable regulating resistance in series with it. When the ohm-meter or galvanometer indicates that the required resistance is reached, the current is immediately turned off, and the filament is taken out and a fresh one put in.

The process about to be described, in which pentane is used, is capable of giving the filaments a very thin coating of deposited carbon. A circular brass base-plate, A (Fig. 12), turned perfectly true and free from flaws is fixed to the bench. A small hole, one-eighth inch in diameter, passes through the centre. Into this hole is screwed and soldered the end of a brass tube B, which passed through the bench or table. Upon A is a flat rubber ring, C. The glass receiver D, which may be about 11 inches high and 2½ inches in diameter, stands on the rubber ring. The whole of the clip arrangement on the top of the receiver can be lifted off. It consists of a vulcanite disc, E, underneath which is another rubber ring. Through the disc pass two brass rods, G G, ending in the spring clips

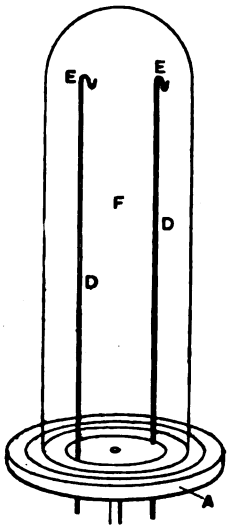

FIG. 12.

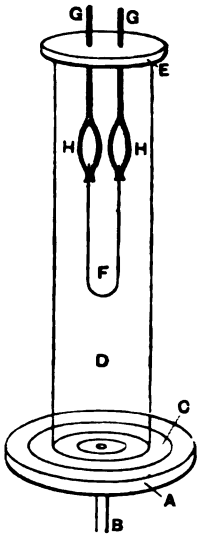

FIG. 13

H H, for holding the filament F. Four of these apparatus may be fixed close to each other on the same bench, so as to be operated by one person.

Another arrangement is that shown in Fig. 13. Two metal rods, D D, pass through the base plate A, from which they are insulated, and terminate in the hooks E E. A glass shade, F, covers the whole and stands on the rubber ring on A. The filament is held in a clip such as that showed in Fig. 14. The metal parts C C are insulated from each other by mica, A, bound round with metal B. The clip is hung by the eye-pieces D D on the hooks E E (Fig. 13). Mica should be used for the insulation, as other insulating materials may not be able to stand the heating to which they will be subjected during a prolonged flashing.

Fig 15 is a diagram of the vacuum connections. A A', B B' are the bases on which the receivers stand. The arrangement shown is such that A A' can be worked while B B' are being pumped. There is a syphon mercury vacuum gauge C C C C, about six or eight inches high, for each receiver. This kind of gauge is necessary. A barometer tube gauge is too large and clumsy, and is apt to get broken when the vacuum is destroyed, owing to the impact of the mercury with the top of the tube. Moreover, the scale must be a movable one, so that it can be raised or lowered according as the barometer

Digitized by Google

rises or falls, or the true state of the vacuum in the receivers cannot be known. A syphon gauge always shows the actual state of the vacuum, whatever the atmospheric pressure happens to be. D D′ are two-way cocks connecting A to A′ and B to B′. E E′ are three-way cocks which will connect A A′ or B B′ either to the air by F F′, or by the three-way cock G to the pentane resevoir H, or to the vacuum pump K. The method of working is as follows :—

Filaments to be flashed having been put into the receivers on A A′, the cock D being open, the cock E, as shown in the diagram, connects A A′ to G, and through G to the vacuum

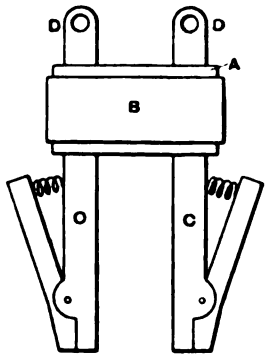

Fig. 14.

pump, which may be at a distance in the engine room of the factory, and driven by power. A vacuum is soon produced in the receivers on A A′, and when it arrives at about six inches pressure of mercury its progress can be watched on the gauge C C.

It is essential in this method of flashing that all joints, pipes, and cocks be absolutely air-tight. It might be supposed that arrangements such as shown in Figs. 12 and 18 would not be air-tight. Standing with their own weight on the base-plates the glass cylinders would not be tight, but, as soon as the vacuum is turned on, the pressure of the air forces the cylinder

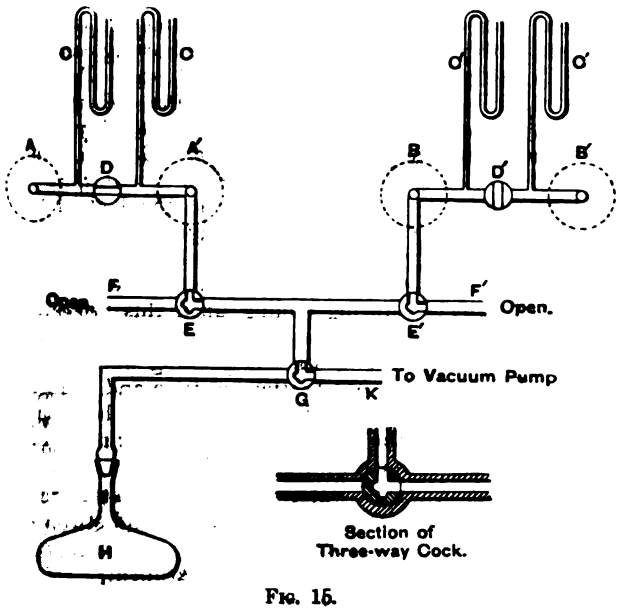

Fig. 15.

so tightly against the rubber rings that the arrangement does not leak, and, if properly made, it will hold a vacuum for hours. Of course, the arrangement shown in Fig. 18 with only one rubber joint is less likely to leak than the one (Fig. 12) where the filament is inserted through the top of the cylinder.

The vacuum is applied until the difference in level of the mercury in the gauges is about half an inch. This is as far as most mechanical air-pumps will go in practice. The cock G is then turned, disconnecting the receivers A A′ from the vacuum pump, and connecting them with the reservoir H, which has previously been partly filled with pentane. Pentane vapour now passes from H along the tubes into the receivers A A′. This is apparent by the increased pressure indicated by the gauges C C. The vapour should be allowed to enter until the gauges show five inches difference in level. The cock G is then turned back again, connecting A A′ with the vacuum pump, and the vacuum is again reduced to about 1½in. by the gauges. The cock E is then turned so that A A′ are disconnected entirely. The cock E′ is now turned so that B B′ are connected through G to the vacuum pump. The condition of A and A′ is now the same, and the cock D is turned, so that A is shut off from A′. Current is now applied to the filament in A. The increase in temperature of the gas in the receiver, produced by the heating of the filament, causes increased pressure, and the gauge shows a decreasing vacuum. The filament is brought to a bright white heat, at which it is maintained by means of the regulating resistance, until the indicator which is used shows that it has received a sufficient coating of carbon. The filament in A′ is then treated in the same way. The cock D may then be opened, and E turned so as to admit air through F into A and A′. The filaments are then taken out and fresh ones put in. The same process is then repeated with the filaments in B and B′. While the flashing is going on in one side of the apparatus the other side is being pumped.

This may appear a complicated arrangement of pipes and stopcocks, but with a little practice it can be worked very quickly. With the apparatus shown in Fig. 18, the electrical connections with the different filaments is made by means of a switch, while with the other form (Fig. 12) one clip on the end of a flexible wire makes connection to the wires G G. By this latter method the chances of turning the current on to the wrong filament are less than with the switch arrangement, as the operator is apt to forget to put the switch over, whereas in the other arrangement the clip must be removed from the top of the apparatus before the filament can be taken out.

Hard, white, deposited carbon has only about one-tenth of the specific resistance of carbon made from amyloid, the resistance of the deposited carbon of that kind being about 350 microhms per cubic centimetre, and that of amyloid carbon 3,500 microhms at a temperature of from 6 to 2 watts per candle power.

At the ordinary temperature of the air the deposited carbon is about two and a-half times greater, and the amyloid variety one and a-half times only.

(To be continued.)

BOILER TESTING.*

It is most desirable that all trials should be so conducted and recorded that comparison with other similar trials may readily be made. All instruments employed—such as pressure gauges, thermometers, &c.—should be compared with standards before and after the trials; a careful analysis of two or three representative samples of the fuel used should be made, or, in default of this, a well-known coal of good quality, such as Nixon's Steam Navigation, of which the constitution has been tolerably well ascertained, should be used.

In complete evaporative trials it is usual to form a heat balance-sheet as below:—

Heat received.	B.T.U.	Per cent.	Heat expended.	B.T.U.	Per cent.
To calorific value of coal.....	Q	100	By dry steam	Q_s	
			„ priming water ...	Q_p	
			„ exhaust	Q_e	
			„ incomplete combustion	$Q_{i.c.}$	
			„ radiation, &c.....	Q_r	
			„ losses unaccounted for	Q_u	
	Q	100		Q	100

It is often considered sufficient to ascertain the weight of feed water evaporated per pound of coal, neglecting errors due to possible priming; but in careful evaporative trials observations are made of the durations of the experiments, the quantities and analyses of the coal used, the quantities of ash remaining, the quantities and temperatures of the feed water, the steam pressures, the amounts of priming water in the steam, the temperatures and analyses of the flue gases, and of the losses of heat by radiation, &c., from the boilers.

Coal.—At each trial two or three small quantities (a few pounds each) of the coal should be weighed; then dried and weighed again to determine the average amount of moisture present per pound of undried coal (*i.e.*, coal as used in the trial). Prior to analysis the samples of coal should be thoroughly dried as the working out of results of trials with coal of the same kind, but containing different amounts of moisture, is thereby facilitated.

The principal active constituents of coal are carbon, hydrogen, and oxygen; and denoting the weights of these in pounds per pound of *dry* coal by C, H, and O respectively, we have:

$$Q_1 = 14545\,C + 62032\,(H - O/8),$$

where Q_1 is the *total heat of combustion* in British thermal units per pound of *dry* coal. A part of this total heat of combustion is used up in vaporising the water formed by combustion of the hydrogen, and must be subtracted from Q_1 in order to give Q_2, the *calorific value* of one pound of *dry* coal in B.T.U.; if the temperature of the coal is t'°F, and if—for definiteness—the water formed is taken to be vaporised at this temperature, we have

$$Q_2 = 14545\,C + (52007 + 6{\cdot}255\,t')\,H - 7754\,O.$$

If at any trial each pound of undried coal is found to contain on an average q lb. of water (and, consequently, $1 - q$ lb. of dry coal), the *calorific value* of the *undried* coal (Q) is obtained by subtracting from $Q_2\,(1 - q)$ the heat required to evaporate q lb. of water from and at t'°F: hence

$$Q = (1 - q)\{14545\,C + (52007 + 6{\cdot}255t')\,H - 7754\,O\} - (1113{\cdot}9 - 0{\cdot}695t')\,q;$$

and since t' will generally be from 60°F to 70°F, Q may be found with sufficient accuracy from the formula

$$Q = (1 - q)\,(14500\,C + 52400\,H - 7750\,O) - 1070q.$$

It is convenient to weigh out the coal to be used into sacks containing 100lb. or 112lb. each, and these sacks may with advantage be numbered and ticketed to avoid risk of error; the time at which each sack is used during a trial should be noted, as this enables a graphic representation of results to be made. If the duration of a trial exceeds eight to ten hours, either of the two following methods of ascertaining the quantity of coal properly debited to the test may be employed:—

(*a*) The boiler is thoroughly heated up* and steam raised to the normal pressure with unweighed coal; then the fire is drawn and the trial commenced with weighed coal and a small weighed quantity of dry wood. At the conclusion of the trial the fire is again drawn, and this when cool is divided into incombustibles (clinkers picked out by hand and small ashes passing through, say, a half-inch sieve), and combustibles (the remainder). The latter may be taken as good fuel and deducted from the total quantity thrown on the grate. An allowance must be made for the wood used in re-lighting, and 2¼lb. to 2½lb. of dry wood may be taken as equivalent to 1lb. of average coal.

(*b*) The boiler is thoroughly heated up, steam raised to the normal pressure, and the condition of the fire carefully noted; the trial is then commenced with weighed coal; at the conclusion of the test care must be exercised to leave the fire in the same state as at the beginning of the test. This latter method is not so accurate as the former, especially in trials of short duration, on account of the difficulty of judging whether the fire is in the same condition at the end as at the beginning.

* Sufficiently to get the boiler and brickwork to its ordinary working temperature; this may take two or three days if the boiler has not been recently used.

In all cases ashes which fall through the grate during the trial should be thrown on again to ensure complete combustion, and the clinker and ash should be weighed.

Steam Pressure.—This should be noted at definite short intervals throughout the trial, unless a recording pressure gauge is used. The temperature of the steam, corresponding to the observed pressure, may be obtained from tables, or by the formulæ.

Feed Water.—This should invariably be measured directly in tanks, and not estimated from the speed and capacity of a pump. The tanks employed, from which the boiler should be fed alternately, may be calibrated in the first instance by filling from cans of known capacity; and it is desirable to note the quantity of feed water supplied to the boiler at definite intervals (say every half-hour) during the trial, and not merely the total feed. Care should be taken that the height of the water in the boiler gauge-glass is the same at the end as at the beginning of this trial.

If W_f = weight in lbs. of feed water supplied to boiler per hour,
t = mean temperature in °F. of feed water,
T = mean temperature in °F. of steam and priming water,
W_c = weight in lbs. of coal burnt per hour,
w = weight in lbs. of priming water per lb. of wet steam or per lb. of feed water (*see* Priming Water in Steam),
U′ = evaporation in lbs. of wet steam (or feed water) per lb. of coal,
U = evaporation in lbs. of dry steam per lb. of coal,
Q_s = heat in B.T.U. given to U lbs. of dry steam,
Q_p = heat in B.T.U. given to U′w lbs. of priming water.
E = efficiency of boiler;

then $U' = W_f/W_c$,
$U = W_f(1 - w)/W_c$,
$Q_s = U\,(1113{\cdot}9 + 0{\cdot}305\,T - t)$,
$Q_p = U'w\,(T - t)$,
$E = Q_s/Q$;

where Q is, as previously, the calorific value in B.T.U. of 1lb. of undried coal.

Priming Water in Steam.—To determine the weight of priming water per lb. of wet steam is rather a delicate operation, and demands a considerable amount of care to obtain reasonably accurate results. The following calorimetric method is fairly good if carefully carried out. Take a can capable of containing, say, 250lb. to 300lb. of water, and suspend it by cords inside a larger vessel (preferably metal) so that it hangs clear and is completely protected from draughts. Weigh into the smaller vessel, say, 200lb. of water, and note the temperature; then inject steam from the boiler into this water, and note the temperature every quarter-minute or so, stirring thoroughly the while. When the temperature has risen 40° F. to 60° F. cut off the steam, and note the temperature at short intervals during cooling until this becomes very slow. Then weigh the water and condensed steam carefully to ascertain the quantity of steam and priming water which has been injected. From the observations of time and temperature during heating, and also during cooling, the heat lost by radiation, &c., during the first part of the experiment may be approximately determined, as described later.

If W_1 = weight in lbs. of water in the calorimeter including water equivalents* of the inner vessel and stirrer at the beginning of the experiment,
W_2 = Ditto ditto at the end of the experiment,
t_1 = temp. in °F. of water in calorimeter at the beginning of the experiment,
t_2 = Ditto ditto when steam is cut off; this will be the highest observed temperature if the stirring is thoroughly done,
P = absolute (gauge + 14·7) pressure in pounds per sq. in. of the steam,
T = temperature in °F. of steam at absolute pressure P,
L = latent heat in B.T.U. of water at T °F.,
h = heat lost by radiation &c., from calorimeter, during heating by injection of steam, in B.T.U. (*see* later for means of approximately determining h),

* The water equivalent of the inner vessel is the product of its mass into the specific heat of its material, and similarly for the stirrer.

Digitized by Google

w' = equals total weight in lb. of priming water carried by steam into the calorimeter,

w = weight in lbs. of priming water per lb. of wet steam or per lb. of feed water;

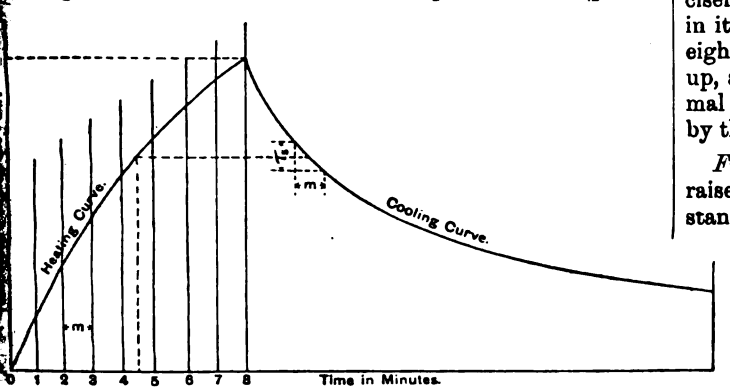
n $w' = (W_2 - W_1) - \{W_1(t_2 - t_1) - (W_2 - W_1)(T - t_2) - h\}/L$;

l $w = w'/(W_2 - W_1)$.

To appoximately determine h construct curves of time and nperature for both the heating and cooling experiments (*see* ure), and divide the duration of the heating experiment o eight to twelve equal periods of, say, m minutes each; the t lost in any given one of these heating periods may be en as proportional to the fall of temperature in that cooling iod of m minutes which has the same mean temperature as the ting period considered—thus in the figure the loss of heat the fifth heating period is proportional to τ_5 °F., which is the l of temperature in the cooling period of m minutes, having e same mean temperature as the fifth heating period. The al heat lost in the heating experiment (h) will be propornal to the sum of the τ s, obtained as described, for all the ting periods, and will be given approximately by the formula

$$h = \tfrac{1}{2}\{W_1 + W_2)\,\Sigma(\tau)\}.$$

Flue Gases.—At intervals during the trial the temperature of flue gases should be taken*, and samples collected (perfer-



ly over brine to diminish the absorption of CO_2 as much as ssible), and analysed. The exhaust gases analysed are dry, e., without the steam previously present with them in the ues and chimney, and consist practically entirely of carbon ioxide, carbon monoxide, oxygen, and nitrogen. If C, H, and represent (as previously) the weights in lbs. of the carbon, ydrogen, and oxygen respectively present in 1lb. of *dry* coal, the weight in lbs. of water in 1lb. of undried coal, and if

a = Weight in lbs. of CO_2 per lb. of dry exhaust gases,
b = weight in lbs. of CO per lb. of dry exhaust gases,
c = weight in lbs. of O per lb. of dry exhaust gases,
d = weight in lbs. of N per lb. of dry exhaust gases,
t' = mean initial temp. in °F of coal (*see* earlier),
t'' = mean temp. in °F of exhaust gases on leaving boiler flues.
Q_e = heat in B.T.U. carried up chimney and lost by exhaust gases per lb. of coal,
Q_{ic} = heat in B.T.U. lost by incomplete combustion, as manifested by presence of CO, per lb. of coal,

hen the weights in lbs. of the dry exhaust gases and of the team accompanying them are $\{77C(1-q)\}/\{3(7a+11b)\}$ and $q+9H(1-q)\}$ respectively per lb. of undried coal burnt; ence, taking the mean specific heat of these gaseous products rom the coal at 0·238 and the heat of combustion of carbon urnt to CO as 4452,

$$Q_e = 0{\cdot}238\,(t'' - t')\left[(1-q)\left\{9H + \frac{77C}{3(7a+11b)}\right\} + q\right] \text{B.T.U.}$$

$$Q_{ic} = 111{,}000\,C\,b\,(1-q)/(7a+11b).$$

Further, the weight of air actually used per lb. of undried coal is $\{100\,C\,d\,(1-q)\}/\{3(7a+11b)\}$ lbs.†

* When the temperature does not exceed 650° F. a mercurial thermometer may be used; for temperatures above 650° F. some form of pyrometer must be employed.

† This is also represented by the expression—

$$\frac{100(1-q)}{23}\left\{\frac{C(56a+44b+77c)}{3(7a+11b)} + 8H - O + \frac{8q}{9(1-q)}\right\},$$

which affords a check on the analysis.

Radiation Experiment.—This consists in observing the quantity of coal required to maintain the normal steam pressure when the boiler stop-valve and feed-valve are closed, the coal used per hour being measured precisely as in the evaporative trial already described. The firegrate area is sometimes reduced by bricks, as in the boiler trials of Messrs. Bryan Donkin and Kennedy*, so that the conditions of firing may be equally favourable with those in the evaporative test. Care should be exercised during this trial that the safety valve does not lift.

If w_1 = weight in lbs. of coal used per hour in the evaporative test,
w_2 = weight in lbs. of coal used per hour in the radiation test,
Q_r = heat in B.T.U. lost by radiation, &c., per lb. of coal used in the evaporative test;
then $Q_r = w_2\,Q/w_1$ very approximately.†

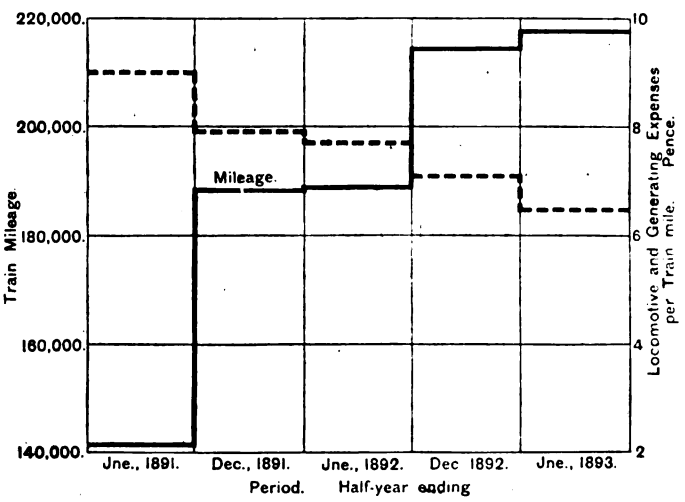
Heat Losses Unaccounted for.—These are obtained by difference,
and if Q_u = heat in B.T.U. lost, and unaccounted for explicitly, per lb. of coal used in the evaporative test;
then $Q_u = Q - (Q_e + Q_p + Q_t + Q_{ic} + Q_r)$.

Fuel for Keeping Steam on Light Load.—This trial is precisely similar to the radiation test, except that the fire-grate is in its normal condition as regards area. The trial should last eight to ten hours, the boiler having been previously heated up, and the coal in lbs. per hour required to maintain the normal steam pressure is simply the total quantity used divided by the duration of the test in hours.

Fuel for Raising Steam.—The quantity of fuel required to raise steam depends on the length of time the boiler has been standing unused; hence this time should be definitely stated in every record of such a test. The wood used for lighting up should be allowed for, and—on the boiler having been heated up and steam raised to the normal pressure—the fire should be drawn, and the *combustibles* then on the grate deducted from the total fuel used.

THE CITY AND SOUTH LONDON RAILWAY.

The steady increase in the train mileage of the City and South London Railway and the equally steady decrease in the locomotive and generating expenses per train mile run are shown in a striking manner on the accompanying diagram. The



reduction of the locomotive and generating expenses from 9d. to 6·48d. in less than three years is a remarkable instance of the saving virtues of actual experience, and it should embolden capitalists who are hesitating about sinking their money in electric railway tubes.

* See *Engineering*, Vol. 50 *et seq.*, for accounts of these trials, the mode of presenting the results of which forms an admirable model for similar trials.

† Probably Q_r is actually rather greater than this.

TRANSMISSION OF POWER AT BIBERIST.

The following particulars of an application of water-power for the purpose of driving a paper mill at a distance of 20 miles from the fall, may be of interest. The owners of the Biberist Paper Mills finding that, on account of the need for increased power at the mills, the neighbouring water supply was inadequate, determined upon utilising the surplus of the water power which was employed in driving two other of their paper mills on the banks of the Suze. One of these mills is situated at Frinvilliers, in the Bernese Jura, and the other at Ronchatel, about ½ mile further up the stream. The fall between the two is about 45ft.; and, by conveying the tail water of the upper mill through a canal, cut partly in the solid rock and partly sustained by masonry, this fall is utilised without injuring the supply of power to the lower mill. The flow of water varies considerably according to the season; but, throughout the greater part of the year, there is a surplus of not less than 400 H.P. Acting upon the advice of Prof. Denzler, of Zurich, the managers of the mills decided to electrically transmit this power to the Biberist mills by means of a high-pressure current carried through an aerial line over the mountains.

The work was placed in the hands of the Compagnie de l'Industrie Électrique, of Geneva, and was carried out in the following manner, under the direction of M. Goichot, their engineer.

At the generating station at Frinvilliers a 400 H.P. turbine, constructed by MM. Escher, Wyss, and Co., of Zurich, has been placed, the turbine working on a vertical axis at a normal speed of 120 revolutions per minute. This turbine is geared, by means of a bevel wheel and two pinions, to two continuous current dynamos of the Thury pattern, which are arranged respectively on the left and right of the turbine. The dynamos run at a normal speed of 275 revolutions per minute, and their output is 40 amperes at 3,300 volts each. They are connected in series, giving the extraordinarily high pressure (for continuous-current closed-coil machines) of 6,600 volts. The armature winding is of the Gramme ring type, and the magnets, which are entirely of wrought iron, have six poles. The commutators are 3ft. in diameter, and consist each of 442 sections of hard-drawn copper insulated with mica. There are 18 carbon brushes on each machine, arranged in six sets of three abreast. The dynamos are supported on adjustable bolts placed on porcelain insulators, and an insulating floor is provided all round the machines. The weight of each machine is about 31·5cwt., and, under test, a commercial efficiency of nearly 93 per cent. has been obtained.

The two motors at the Biberist mills are also connected in series. They are identical with the generators, and each delivers 155 H.P. at 200 revolutions per minute, giving a total efficiency of the entire plant of about 78 per cent. The two lines joining the generators with the motors are constructed of bare stranded copper, 7mm. in diameter, equivalent to No. 2 S.W.G., their total resistance causing a drop of 600 volts, or 9 per cent. The lines are carried on wooden poles and, their exposed position rendering them very liable to be struck by lightning, they are protected by simple lightning arresters placed on many of the poles, and by condensers and impedance coils placed at the two stations at the ends of the line.

THE PROPOSED MUNICIPALISATION OF THE TELEPHONES AT GLASGOW.

At the meeting of the Glasgow Town Council, on Thursday of last week, Mr. STARKE, in moving the approval of the minutes of the Telephone Committee, and of the relative minute of the Finance Committee, said that the Telephone Committee was appointed a few months ago to consider the municipalisation of the telephones. The Committee had given the subject the fullest consideration, and they had resolved to recommend that an application be made to the Postmaster-General for a license to supply the community with an efficient telephone service. A deputation of the Telephone Committee afterwards met with the Finance Committee, for the purpose of seeing as to ways and means. The Finance Committee heard their statement, and gave it a hearty and generous response, and "resolved to concur in the recommendation of the Special Committee that an application should be made for a licence. They further agreed to recommend that the Corporation should advance the sum necessary to start the system." If one might judge from what had appeared in the public prints, among the citizens and the outside public generally, there was nothing but the heartiest good wishes towards this proposal. All authorities on the subject were at one in this, that the system they were using in Glasgow and throughout Great Britain was most unsatisfactory—in fact, it was the worst in Europe. It was expensive, and, from the special circumstances in which the Company was placed, it could never be otherwise except on conditions to which the Council would never agree. There was a general feeling that the matter must be taken up by the State or by the municipal authorities in connection with the State. It was becoming that Glasgow, with the *prestige* she held as a bold and successful exponent of municipal enterprise, should step out and be the first in the direction of dealing with the telephone service. The Committee were following the principle of doing for the citizen in his corporate capacity what he could not do so well in his individual capacity. If the telephone system were developed, as it was likely to be if the recommendation were adopted, it would be brought within the reach of the humblest citizen. The present system in Glasgow, which was a single-wire system, was totally unfitted for such a great city. The Company could not improve the present system unless they erected twin wires overhead or got possession of the streets. Suppose they adopted the twin-wire system, they would have the immense crowd of overhead wires duplicated. The only alternative was for the Company to get possession of the streets and lay the wires underground; and this the Corporation would not agree to. As to the financial arrangements 3,500 subscribers at £5 per head would amount to £17,500, and there would be at least 2,000 private instruments, which would make the income £19,500. The working expenses might be reasonably taken to mean 50 per cent. of the revenue, while the Government licence would be 10 per cent. on the net income. Then it was proposed that 5 per cent. should be set aside every year as a sinking fund, so that the whole should be wiped out in 20 years. Allowing £2,000 for sundries, he estimated they would have a clear revenue of between £5,000 and £6,000 per annum.

Bailie ALEXANDER seconded the motion. He had been terribly annoyed lately with the present telephone system. He had been trying since July 21st to communicate by telephone with a firm, and had not yet succeeded.

Bailie PRIMROSE said he entered the room with an open mind, but after listening to Mr. Starke he had come to the conclusion that he asked them to embark on a rash and Quixotic scheme. His intention was to move that the whole subject be remitted to a committee for further consideration, with instructions to report fully and in detail. They had lately municipalised the tramway system, but he denied that this was a parallel case, for the tramways were a monopoly, and they touched civic life at every point. The acquisition of the telephone system was not a municipal but an imperial question. The Government had assumed control of the telegraph system with advantage to the country, and was it not probable that the Government, in acquiring the trunk telephone system, recognised that at no distant date Governmental supervision must be extended? for in the limitations they were imposing they kept the question as simple and easy a one as possible. Mr. Starke said that they were only making an application for a licence to the Postmaster at present, but was it desirable to apply for a licence with their minds half made up, without being fully convinced as to the rudimentary principles involved? Supposing the municipality agreed to establish a telephone system, it would simply involve the community, as it did in Manchester when the Mutual Company existed, in being subscribers to both. That was one great difficulty he saw in municipalising the telephones. If an Act were passed empowering all communities to adopt the telephone system as part of municipal work the difficulty would not end there, because many of the municipalities, probably for reasons of prudence or lack of enterprise, would not avail themselves of it, and what intermediate link were they to have except a national company like the present? He was not arguing for limitation of municipal enterprise; but he was endeavouring to point out that there were hard initial difficulties which Mr. Starke had touched and lightly passed over. In municipalising the telephones they would be at once confronted with the wealthy and powerful opposition of the present company. With regard to the financial proposals, he thought they could, without any breach of courtesy, be described as crude and problematical. What data had Mr. Starke given them that had been endorsed by any specialist? What were they to make of the statement that for a capital expenditure of £15 for each user this service could be provided. He would like to see that statement very authoritatively put down in black and white and the details wrought out. On the bald and unsatisfactory information placed

Digitized by Google

before the Council that day, he felt justified in proposing the amendment he had submitted.

Mr. D. M. STEVENSON supported the motion. He pointed out the powers of telephone companies with regard to carrying wires under streets, and remarked that Bailie Primrose asked for more data, and yet Mr. Starke was stopped because he was giving them too much information. The Corporation must have the monopoly of their streets. He did not suppose that they would give it away to any rival company. Again, there was no likelihood of the State taking possession of the local wires.

Mr. COLQUHOUN said he very seldom differed from Bailie Primrose, but he did so on this occasion. The position Mr. Starke asked the Council to take up was that merely in the meantime of applying to the Post Office authorities for a licence to establish a telephone system. Beyond that there was nothing in the proposal of Councillor Starke that committed the Council to the expenditure of money without having the fullest details before it, and without having the most perfect assurance that money so expended would be profitably expended. What was the Municipality to do when they were being victimised—he could not use a less strong word—by the National Telephone Company? It might be asked, how were they being victimised? In reply, he said that before they could establish an overhead system of electrical tramways they must provide a system of insulation. That position, to put it plainly, was one of the most impudent ever taken by a private company. He did not know what Bailie Paton, the convener of the Tramway Committee, would have to say for allowing the National Telephone Company to get a clause in the Tramway Act making such a thing possible, but the only way in which they could meet the Telephone Company was by taking the step Mr. Starke recommended. He therefore besought the Council to adopt the motion.

Bailie GRAHAM supported Bailie Primrose's amendment. He did not defend the present telephonic service. During the past three weeks his experience had been of the most terrible character, and he had latterly given up using the telephone, as it led to more bad language than he cared to employ. But the proper solution of the question was to press upon the Government the propriety of acquiring the telephone service of the country.

After some discussion, Mr. STARKE agreed to omit the last clause of the motion recommending the Corporation to advance the amount necessary to start the system.

The Council divided, when the motion as amended was adopted by 27 votes, against 21 for the amendment of Bailie Primrose.

ELECTRIC ROCK-DRILLING MACHINERY.*

BY A. L. STEAVENSON.

Ironstone mining in Cleveland has now extended over a period of forty years, during the whole of which the writer has been connected and conversant with its progress.

Electric Drill.—When electricity became applicable, its simplicity and regularity in working seemed to offer an inducement for a trial. With the assistance of Mr. Robert Clough, engineer to the mines and collieries of Messrs. Bell Brothers, the writer designed a drill to be worked by this power.

Dynamo.—The current for working the drills is generated at bank by a compound-wound dynamo, having an output of 20,000 watts, and capable of furnishing a current of 50 amperes at a pressure of 400 volts, when running at 900 revolutions per minute. This dynamo is intended to supply current for working the first section of the plant, namely, three drilling machines. The current required to drive each drill varies, of course, with the hardness of the stone the drill is working in; but it may be taken that under ordinary conditions, and when the voltage at the drills is 300, the current absorbed per drill-motor is about 15 amperes, which is about 6 E.H.P.; and when a dynamometer was applied to the drill bar, 6 H.P. was obtained. The current from the dynamo is taken to a high-tension double-pole switch on the main switchboard, which is of enamelled slate, and has mounted upon it the necessary fuses, measuring instruments, &c.

Cables and Junction-Boxes.—From the switch the current is conveyed down the pit through cables covered with highly-vulcanised india-rubber. The cables are run all the way in-bye on insulators, and are kept well in sight, so that, should a fall of stone occur, the damage can be quickly discovered and set right. The main cables are run to a point at a distance of 1,000 yards from the generator; and then from this point branch cables are run to the different junction-boxes, of which there are six to each drill, commanding twelve working places. The juction-boxes were specially designed to meet the exigencies of the case, and are really a combination of a junction-box, switch, and connecting-plug. The plug is locked in position by a pin, and cannot be withdrawn without first of all lifting the switch, thus preventing sparking and wear on the contacts. Each district to be worked by the several drills is completely wired out and fitted up with these junction-boxes, so that when the drill is moved from one working place to another a box is always to be found within 50 yards distance. The plug at the end of the drill cable is then inserted, the switch on the drill turned on, and within a few seconds the drill is again at work. Much time is saved by this method.

Drilling Machine.—The motor is used not only to drive the drill gear, but also to act as a counter-balance to the weight of the drill itself and its gearing. The motor rotates a shaft, which passes through a long hollow carrying bar, and by a pair of bevel wheels causes a vertical spindle to revolve; and a bevel pinion on the top of the spindle, gearing into a bevel spur-wheel on the boring-bar, rotates the drill. The forward feed of the boring-bar is governed by two pairs of retarding wheels, which are geared in such a proportion as suits the nature of the stone. The drill is carried on a circular bed-plate, which is mounted on the end of the carrying bar, and can be turned round by hand when the binding screw is released. As soon as a hole has been drilled the full length of the screw on the boring bar a split nut is opened, and the boring bar drawn back for inserting a longer drill. In order to reach different heights, the drill can be tilted upwards or downwards by means of a semi-circular arc, which is moved by a worm, By another worm-wheel the upright pedestal can be turned horizontally round its centre. A third worm-wheel turns the long hollow bar which carries the drill.

Motor.—The motors on the drills are shunt-wound, and can easily utilise a current of 20 amperes at 300 volts pressure, giving off about 95 per cent. of what they receive. They are of the Goolden enclosed kind for mining purposes, both the armature and the commutator being completely enveloped in gun-metal cases, which are both gas and dust tight. Even should water pour over them, or a fall of stone occur, they are perfectly protected, and no appreciable damage would be done to them. The brushes used are of special carbon coated with copper. The feed for the brushes as they wear themselves away is automatic, so that they can be run for weeks together without requiring any adjustment or attention. Each drill is provided with a starting switch, placed in the most convenient position on the drill carriage itself, and arranged with resistance coils in such a manner that the drill can be started gradually, and stopped either gradually or instantaneously. Each drill is also provided with a reel of 50 yards of twin flexible cable for the supply and return of the electricity; at the end of the cable is a connecting plug for inserting into the nearest junction-box.

Working.—These electric drills were put into the hands of men who had no previous knowledge whatsoever of electricity; and the day the first drill was put into the mine it was at once set to work at the face, and has been at work ever since. The men are now thoroughly accustomed to the drills, and handle them with the greatest ease. The writer has thus tried almost every method for working drilling machines in ironstone mines, including compressed air, hydraulic power, and petroleum engines; and it is his decided opinion, as the result of this practical experience, that for simplicity in working, ease of transport, speed, facility for extension, and economy in working, the electric drill has proved itself to be in advance of any other mechanical contrivance yet introduced; and that in the future, where power has to be conveyed to any considerable distance for mechanical drilling, electricity will undoubtedly play the predominant part. The entire work was placed in the hands of Messrs. D. Selby Bigge and Co., electrical engineers, of Newcastle-on-Tyne; and Mr. Bigge devoted considerable time with the writer and Mr. Clough to working out and improving the various details of this first attempt at electric drilling in the Cleveland ironstone mines.

Output.—The joint output for one week for two of the three machines has already reached 1,577 tons with 790 holes. From 80 to 100 holes have frequently been bored by one machine in a shift, each hole averaging about 4½ft. deep. The miners are enabled to earn 7s. 7d. each shift, while the stone is got at a cost of 7½d. per ton. Powder is always from one-third to one-half more costly when drilling machines are used than is the case with hand-labour, since it suits better to blow the stone out with a larger number of holes which are quickly and cheaply drilled; this plan also makes the stone fall in smaller blocks, and so saves labour in breaking them up previous to filling.

General results.—In attempting to compare the results obtained with the several drills, the following considerations have to be borne in mind. The conditions of the seam of ironstone affect the output and cost. An open stone admits of fewer holes in one place. Then time is lost in more frequent removals of the drill, and the number of holes drilled per hour is diminished. The cost of the machine itself sometimes represents the whole and sometimes only a fraction of the total cost. Thus a petroleum drill covers the

* Abstract of a Paper read before the Institution of Mechanical Engineers.

Digitized by Google

entire cost of its adoption. But the compressed-air drill in some cases has attached to it an average of more than a mile of pipes, and also requires its engine and compressors, as well as its share of boiler. The electric drill also requires engine and dynamo, with a length of cable depending upon the distance from the shaft; it is still so new that alterations and improvements are being made as experience is gained. The hydraulic drill, although getting its power from natural sources, needs pipes; and the exhaust water has afterwards to be pumped up to the surface. The hand ratchet-drill has been applied as yet in only one or two mines, and the tonnage rates and system of working are not yet finally settled with the workmen.

Subject to these considerations the following comparative statement may be taken to represent generally the results thus far obtained with the several drills:—

Description of drill.	First cost of machine only.	Holes drilled per hour.*	Ironstone got per shift. Tons.
Hand jumper	—	4½ft. in 45 mins.	5 to 8
Hand ratchet-drill ...	£3	not yet known	about 18
Compressed-air drill ...	250	about 8 holes	100 to 130
Hydraulic turbine.....	220	„ 8 „	100 to 130
Petroleum engine	375	„ 8 „	100 to 130
Electric drill	350	„ 10 „	140

* This includes the time lost in moving the machine to different working places.

The length of shift is eight hours from bank to bank, or, say, seven hours at the face. At the Park Mines the drills work two shifts in 24 hours, and at the other mines one shift; and six shifts per week when trade permits.

THE ART OF COMPOSING ENGINEERING SPECIFICATIONS.*

Not long ago, Mr. Theodore Cooper, a member of the American Society of Civil Engineers, and an eminent constructor of bridges, &c., addressed the students of the Rensselaer Polytechnic Institute on the important subject of engineering specifications. Mr. Cooper has had great experience, and in his address the result of practice reacting upon conspicuous common sense and trained ability in engineering business is set forth in the happiest and clearest language. He passes in review all kinds of engineering work, and every method of executing it; and he concludes in favour of the contract system. The importance of the study of specification-writing, however, does not depend wholly upon the continuance of the contract system, for when work is done at first-hand there is just as great necessity for explaining the manner of carrying out plans, and stating the nature and quality of the materials to be used, as when these instructions are to be carried out by a middleman.

Upon the supposition that a contract for any particular piece of engineering work is to be let, in the usual way, the first consideration insisted upon by Mr. Cooper is that the price should be such as will give "the expectation of a reasonable profit to the contractor." This is not to be understood as meaning that the contractor ought to have a profit in any or all circumstances, but only when the condition is observed of a proper and economical execution of the work. "I think you will find it the universal testimony of experienced engineers," says Mr. Cooper, "that, were it within their power, they would never allow a contract to be made which did not contain the expectation" already stated. The speaker was at particular pains to lay stress upon this expression of the business principle in contracting, because, as he says, it is not always kept in mind by professional men, some of whom regard the contractor as the natural enemy of the engineer. In preparing the estimate of any particular piece of work, it is the duty of the engineer, as well as of the contractor, to add to the approximately known elements of cost the reasonable contractor's profit, and also a contingency allowance "proportional to the risks involved and to the unknown elements entering into the execution." Failure to recognise this principle is a source of great injustice as between the parties to a contract. Engineering specifications are defined by Mr. Cooper as consisting of the "detailed particulars supplementing and explaining the plans of any piece of work, and governing the character of the materials and the methods of construction to be used for the same." The object of a specification is further defined as being twofold. In the first place, it is intended to enable tenderers to understand fully the character and extent of the work and what they are expected to supply and to do, in order that they may be able to make suitable estimates upon which to formulate an intelligent and proper tender. Secondly, it is intended to serve as a reference to the plans, in regard to all questions of quality of material and workmanship during execution, in order to prevent misunderstandings between the engineer and the contractor. Nothing serves better, says Mr. Cooper, in obtaining the best class of contractors and obviating friction between engineer and contractor, than a good specification, carefully and clearly expressed. On the other hand, a loosely-drawn and incomplete specification is always an attraction to the worst class of contractors, or those who have no intention of doing an honest job, but will take advantage of every weak point to get all they can out of the contract. Such men frequently tender low for jobs when they see a weak specification, trusting to make "extras" later on, or to be able to skimp in cheap material or work. Mr. Cooper lays great stress upon a matter that is to the full as important in England, with our many local customs, as it can be in America. This is the classification and nomenclature of materials used in engineering and building construction. Where there are several classes of materials and workmanship which are to be paid for at different rates, it is very essential for every class to be properly and clearly defined in language intelligible to a master workman. The use of such general terms as "first-class material," and "best workmanship," &c., as Mr. Cooper says, carry no weight except where they are expressly defined, or are taken in connection with other definite clauses. The average contractor is quick to discover the engineer's want of knowledge of the terms employed in his own specification; and is not unlikely to take advantage of such weakness, if he is an unscrupulous man. All this trouble is avoided when specifications contain plain directions, and the engineer is competent to tell whenever these are being infringed. Mr. Cooper passes on to the consideration of the vexed question of the reserve of disputes respecting the interpretation of a specification or the execution of work to the arbitrament of the engineer. He strikes the true note in giving as his opinion that no engineer has a right to insert in specifications such phrases as "to the satisfaction of the engineer," or "as may be directed," to be afterwards used for obtaining more or better material and workmanship than would be expected from the context of the specifications. They can, however, be fitly used to cover work or material which could not in the circumstances be otherwise defined; or they can be used to relieve the contractor under special conditions, by accepting some other material or work than is specified, if good reasons can be adduced for the change. Contingencies of this kind will often arise; and the great point to be borne in mind is that the reserve of reasonable discretion to the engineer is as much to the interest of the contractor as against him.

With regard to the general framing of specifications, Mr. Cooper counsels adherence to well-proved models, modified, if necessary, for the special purpose. The model must first be carefully studied, in order that its theory and general purport, as well as the meaning of the various clauses, may be understood. The wording of old and clearly-defined clauses is in no case to be tampered with. "A specification is not intended to be a treatise on the refinements of engineering theory, but a practical set of rules and conditions upon which work is to be let and constructed. A specification should therefore be reasonably brief and positive." A general specification need not provide for all the special minor conditions and exceptional cases may possibly occur in practice; but, on the other hand, an accepted model specification is to be regarded as an "accumulative growth," and will contain many requirements that cannot be safely set aside, though they may never come into operation in the case in point. It is therefore safer to maintain them than to create an exception.

Finally, says Mr. Cooper to all young engineers, be content to go on as far as you can in the old ways, by old methods, and with the use of well-tried and common materials. No specification that was ever drafted would get good and proper materials and workmanship if left to itself, or placed in the hands of inexperienced or incompetent persons to execute or administer. A specification also, which contains any extra-refined, new, or severe demands which the aspiring engineer has not the proper experience, time, or assistance to enforce, is a mistake, for it means that the employer will have to pay for something that there is no guarantee of his getting. While, therefore, special works of importance may justify the employment of new methods and new materials, it must be recognised that this means extra inspection and supervision, and a higher run of prices than would be required for customary methods and materials. "Do not attempt to rush into new things until you have exhausted the capabilities of the things which are readily obtainable. For general classes of work you will find it better, both in time and money, to make use of the ordinary methods and those materials which are accessible." These remarks on specifications for engineering works deserve to be studied in every engineer's office in the world.

* Abstract from the *Journal of Gas Lighting*.

RESULT OF TRIALS OF THE "TRUSTY" OIL ENGINE.

Trials have recently been made by Mr. Worby Beaumont of the "Trusty" oil engines of Messrs. Weyman and Hitchcock, Guildford. An engine of the following dimensions was used:—Diameter of cylinders, 7·37in.; length of stroke, 14in.; revolutions per minute, nominal, 248; diameter of fly-wheel, approximate, 5ft. The engine is of the vapouriser type, and works with the oils obtainable everywhere for lamp and other purposes, or with heavy oils. The vapouriser is a simple jacket cast with the separate extension of the cylinder like that common to gas engines. No trouble is experienced with anything in the nature of a deposit. Perfect combustion of the oil vapour produced takes place in the cylinder, leaving no deposit there, the exhaust being almost invisible on a dry day when working with a full load, and quite dry and free from oil in any form. The power of the engine was taken with a rope brake. The indicated horse-power was obtained from diagrams taken with a Tabor indicator. The number of misses, or of strokes made without combustible charge, was frequently taken, and the whole of the oil and water used was weighed.

The duration of the several trials was: Full power, 4 hours; half-power, 2 hours; running light, 1 hour. The intended full power load was 6 H.P., and the brake load was adjusted as nearly as possible to this. The running of the engine was very regular, and when at half-power the speed was within 0·4 of one per cent. that at full power. The oil used in the trials was Royal Daylight, costing in quantities about 4d. per gallon. Its specific gravity was found to be 0·802, one pint thus weighing 1·0025lb. The following is an abstract of the essential results of the trials:—

—	Full power.	Half-power.	Running light.
Brake horse-power	5·98	3·32	—
Indicated horse-power	7·04	5·48	2·72
Oil used per hour, lb	4·90	3·74	2·25
Oil used per B.H.P. per hour, lb.	0·82	1·12	—
Oil used per I.H.P. per hour, lb.	0·69	0·68	0·82

From the preceding figures it will be seen that the cost of working the engine with oil at 4d. per gallon on full-power load is about one third of a penny per indicated horse-power per hour.

In the "Trusty" engine, the ignition of the combustible charge in the cylinder is effected by means of the simple heated tube as commonly used in gas engines, the tube being heated by a lamp fed with oil of the same kind as that used in the engine. The quantity consumed for this purpose is very small, and was found to be 6oz. to 7oz. per hour. With average work the consumption under this head would be about 0·06lb. per indicated horse-power, and a cost per hour for full load of 6 H.P. of from one-sixth to one-fifth of a penny per hour. The total consumption of oil for working the engine on an ordinary full load, including that required for heating the ignition tube, will thus be 0·75lb. per indicated horse-power per hour, costing 0·375d.

The mechanical efficiency of the engine is very high, especially for engines of the four cycle class, and the absolute heat efficiency is very remarkably high.

CORRESPONDENCE.

ELECTRO-CHEMICAL EFFECTS DUE TO MAGNETISATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the *Engineer* of July 28th (Notes and Memoranda) I noticed an announcement of a series of investigations carried on by Lieut. George O. Squier, in the Laboratory of John Hopkins University on the above interesting subject.

I am glad Lieut. Squier has undertaken a research in this direction. I think it desirable, however, to state that he has not been the first to observe these effects of magnetisation. Several years ago I had the privilege of observing and investigating these obscure magnetic phenomena in a series of researches, the results of which were embodied in a number of Papers read before the Royal Society, London, under the title of "Electro-chemical Effects on Magnetising Iron," Parts I., II., III., IV., and which are published in the *Proceedings* of the Royal Society, 1887, 1888, 1889, and 1892 respectively.

I think I ought to mention this to prevent any question of priority arising, though at the same time I heartily congratulate Lieut. Squier on the results he has obtained, and wish him every success in his further investigations.—Yours, &c.,

THOS. ANDREWS, F.R.S.

Wortley Iron Works, near Sheffield,
August 8, 1893.

PAINT AS AN INSULATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the statement of Sir Frederick Bramwell, that the paint on water pipes would act as an insulator, I may tell you that we have used for two years "Edison-compound" as a paint on our lead-covered branch lines, and that we find the use of such paint very effective in preventing corrosion and the early destruction of the lead covering. It may be observed that, to ensure durability, the painting has to be done several times, so as to give to the layer a certain uniformity and thickness. Unpainted lead is destroyed within a few years, whilst "compound"-coated cables do not show any signs of corrosion.—Yours, &c.,

ETIENNE DE FODOR,
Manager Athens Electric Central Station.

Athens,
July 26, 1893.

LEGAL INTELLIGENCE.

Marshall v. the South Staffordshire Tramways Company.

This case came before Mr. Justice Kekewich in the Chancery Division on Saturday last, and the following is abstracted from *The Times*:—

This was a motion by the defendant, Mr. William Somers Leo Schuster, for the removal of Mr. William James Carruthers Wain, who had been appointed in the action joint-receiver and manager of the defendant Company's undertaking on behalf of the plaintiffs, who were debenture-holders of the Company. Mr. Schuster had been added by the Court a defendant on behalf of debenture-holders, who did not agree that they were properly represented by the plaintiffs. Mr. Wain was Chairman of the defendant Company, and it was said he was interested in other companies, especially the Electric Construction Corporation, who had contracted to supply the defendant Company with electric traction upon terms which, it was stated, the Directors of the latter Company ought not to have entered into. It was accordingly alleged that Mr. Wain did not hold that independent position which, on behalf of the debenture-holders of the defendant Company, he ought to hold.

Mr. Justice KEKEWICH said the motion was entirely misconceived. Mr. Wain had been accepted both by the plaintiffs and by the defendant Company as receiver and manager. Mr. Wain was appointed by consent, and his lordship could not now decline to recognise the appointment, and, therefore, he would not interfere with him on that ground. There was one serious allegation, namely, with regard to Mr. Wain's connection with the Electric Construction Corporation. He was, and had been, closely connected with the Corporation, who were working the defendant Company's tramways under a contract which had been attacked. That contract did seem to his lordship, on looking at it, to be a contract of an extraordinary character, and it was quite right that this contract should be thoroughly investigated. It was desirable that the Court should have the assistance of an officer entirely unconnected with the Corporation, and that might have been a reason for not appointing Mr. Wain now to be a receiver and manager. It was too common for the office-bearers of one company to be connected with another company which was mixed up in business with the Company of which they were the office-bearers. It might be serious if Mr. Wain were standing alone as sole receiver and manager, uncontrolled except by his position as receiver and manager. In that case his lordship should have been inclined either to remove him or to associate with him some independent person, and not the less because he was connected with persons deeply interested in the success of these tramways. But this must be borne in mind, that Mr. Wain was associated with Mr. Sully, an accountant, whose duty it was to look after his colleague and see that the interests of the debenture holders were protected, and his conduct looked into. But there was a much more important matter than that. His lordship had before him Mr. Schuster, who was as hostile to the plaintiffs as could be, and was determined that neither Mr. Wain nor Mr. Sully should neglect their duty, and his lordship relied on Mr. Schuster taking care to see that Mr. Wain did not act in the interests of the shareholders of the defendant Company or of the Corporation. His Lordship did see that this contract with the Corporation required jealous investigation, and that the office of receiver and manager must be conducted with considerable care, and if, as the action proceeded, he saw the slightest reluctance on Mr. Wain's part or neglect of duty, he should not hesitate to remove him. The motion to remove him now upon the grounds which had been put forward was misconceived, and must be refused. There was not the slightest reason why the conduct of the action should be given to Mr. Schuster as had been asked. It was to the advantage of all concerned that he should be a watchful defendant, and left in the position of a cat watching a mouse. The motion must be refused. The plaintiffs would have their costs in any event. Mr. Wain would have no costs. The costs of the defendant company would be costs in the action.

Digitized by Google

Hall v. Vaughan.

This case, which came before Mr. Justice Kennedy and a special jury at the Liverpool Assizes on Thursday of last week, was an action by the plaintiffs, Messrs. A. Hall and Co., Liverpool, against Mr. J. Vaughan, of Dolgelly, to recover £665 damages for breach of contract. Messrs. Hall and Co., the plaintiffs in the action, have supplied us with particulars of the action, of which the following is an abstract:—

Early in December last plaintiffs supplied an estimate for lighting defendant's mansion, which was accepted, the plaintiffs immediately preparing to execute the work, and contracting with other manufacturers for the turbine and generating plant. After a few weeks (it is alleged) the defendant, without consulting Messrs. Hall, appointed as his consulting engineer a gentlemen who is a competitor in trade. The plaintiffs advised the defendant that, having already undertaken the work and accepted all responsibility, they could not recognise the authority of any engineer, but were willing that defendant should have the installation examined and tested before accepting the same. The defendant, however, would not allow the plaintiffs to commence the erection of any part of the installation, and after some delay, during which the defendant sent inquiries for various particulars of the work, he finally refused to allow plaintiffs to carry out their contract. The plaintiffs, therefore, sued for damages, and when the case came on the defendant's counsel offered to compromise the matter by paying £450 and costs, and withdrawing any imputation upon plaintiffs' ability to carry out the work. This was accepted, and all litigation in the matter is now at an end.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Gas and Lighting Committee of the Bolton Corporation announce in our advertisement columns that they are prepared to receive tenders for the supply and laying of high and low-tension mains. Specifications and forms of tender may be obtained from Mr. J. H. Rider, the Borough electrical engineer, and tenders must be sent to Mr. Alderman Miles, the Chairman of the Gas and Lighting Committee, not later than September 16th.

TENDERS ACCEPTED.—The Ealing Local Board have accepted the tender of Messrs. Neil, of Burdett-road, London, E., for the construction of the central station building, boiler house, &c., the amount being £7,963.

———The Markets and Gas Committee of the Blackpool Town Council have accepted the tender of the Brush Electrical Engineering Company (Limited), for lighting the new covered market by electricity.

——— The contract for the electric lighting of Liége has been ecured by the Compagnie Internationale d'Electricité, owners of the Pieper system.

APPOINTMENTS VACANT.—The Electricity Supply Company for Spain (Limited) require an assistant electrical engineer for their Madrid station. Some particulars appear in our advertisement columns, and applications must reach the Secretary, 15, St. Helen's-place, E.C., not later than the 15th inst.

APPOINTMENT.—Mr. E. T. Ruthven Murray has been elected borough electrical engineer by the Aberdeen Town Council.

PERSONAL —Mr. Stephen Sellon has joined the technical staff of the Electric Construction Company (Limited).

——— Mr. Johnson, of the Sheffield Electric Light and Power Company, sailed by the "Britannic" on Wednesday for New York *en route* for Chicago.

——— *London* this week gives a biographical sketch, with portrait, of Mr. Spencer Chadwick, the well-known auctioneer, in the course of which it says:—"In the electric lighting world Mr. Spencer Chadwick has had much to do ever since it came into practical use in London. From his designs and under his directions one of the first public installations, if not the first, was established in the Strand, now known as the Charing-cross and Strand Electricity Supply Corporation, of which company he is chairman. He is also chairman of two other electric lighting companies, and he is practically the sole owner of the Woking Electric Supply Company, now lighting a very large district."

BANKRUPTCY.—A first and final dividend of 3s. 4¾d. in the £ has been declared, payable at 15, Victoria-street, Liverpool, in the estate of Messrs. Cox, Robinson and Co., lately trading at 8, Strand-street, Liverpool, as electrical engineers. In the separate estates of the members composing the firm, Mr. Charles W. Cox and Mr. F. G. Robinson, first and final dividends have been declared of 4s. 3½d. and 8d. in the £ respectively.

LONDON METALLURGICAL COMPANY, LIMITED (IN LIQUIDATION).—The statement of affairs in this failure has been issued, and the estimated deficiency of assets to meet the liabilities of the Company (subject to cost of liquidation) is £1,936. 15s. 11d. The total liabilities expected to rank for dividend is £11,820. 18s. 1d., and the estimated amount available £9,884. 2s. 2d., showing the estimated deficiency as set out above. The first meeting of creditors will be held at the Inns of Court Hotel, Lincoln's Inn Fields, W.C., on the 15th inst. at 11 o'clock, and proofs must be lodged with the Official Receiver, 33, Carey-street, Lincoln's Inn, W.C., not later than 12 o'clock on the 14th inst.

LAW'S ELECTRICAL APPLIANCES COMPANY (LIMITED).—A meeting is called for September 6th, at 4 p.m., at Messrs. Davidson and Morriss's, 40 and 42, Queen Victoria-street, E.C., to receive an account of the winding up.

MESSRS. ERNEST SCOTT AND MOUNTAIN (LIMITED).—The contract for lighting the Heckmondwike Boot and Shoe Factory for the Co-Operative Wholesale Society of Manchester has been placed with this firm, as have also the lighting of the Leicester Co-Operative Society's premises and the Seaham Harbour Co-Operative Society's buildings.

MR. L. H. BLOOMFIELD.—We are informed that Mr. L. H. Bloomfield has been appointed agent for the "Excelsior" carbons, manufactured by Herr W. Grüdelbach, of Dinslaken-am-Rhein, Germany, and that he also represents several of the largest Continental makers of porcelain insulators, lamp holders, switches, and switchboards, measuring instruments, accumulators, &c. Mr. Bloomfield is also agent for Messrs. O. L. Kummer and Co., of Dresden.

MESSRS. SCHUCKERT AND CO.—The Chicago Exhibition catalogue of this firm of German electrical engineers contains a succinct account of the growth of their vast manufacturing business, and gives some very effective pictures of the exterior and shop-interiors of their works and of various central stations which they have equipped. The latter half of the catalogue is devoted to illustrated descriptions of the plant manufactured and supplied by Messrs. Schuckert and Co.

MASCHINENFABRIK OERLIKON.—We have received two illustrated pamphlets from the Maschinenfabrik Oerlikon describing their machinery for the transmission of electric power. One of these *brochures* deals with the Drehstrom system, giving tabulated data of the generators, motors, and transformer plant; and the second contains particulars of continuous-current dynamos, motors, and regulating apparatus, and also of a lathe which is designed to be driven by an electromotor and worm gear, the motor being built on to the side of the lathe bed.

COOKING BY ELECTRICITY.—An exhibition of electric cooking apparatus was given on Friday at the offices of the Manchester Edison Swan Company (Limited), when a dinner of five courses was cooked by electricity in the presence of a number of guests, who watched the process with great interest. We understand that Mr. Fawcus, the manager of the Company, is receiving a large number of orders for the installation of cooking apparatus in the district.

MONEY-SAVING APPLIANCES.—Messrs. Wells and Co. send us their new list of waste oil filters, oil feeders, lamps for engine tenders, file handles, oil bottles, soldering lamps, &c. The various appliances manufactured by this firm are in use in the chief Government departments, and a claim is made that more than a million are in use all over the world.

ELECTRIC COAL-CUTTING MACHINERY.—The dispute in the coal trade is bringing into prominence the question of the introduction of electric coal-cutting machinery in the mines in the Midland district.

ELECTRIC LOCOMOTION ON ROADS.—Mr. W. Ballantyne, President of the Road Surveyors' Association, speaking at the annual meeting of the Association recently held at Edinburgh, gave a history of the roads in this country, and said that the Roads and Bridges Act had been productive of a large amount of good. If electricity were applied to locomotion it was probable that some of the traffic over the railways would be transferred to the roads.

"ELECTRICITY IN THE SERVICE OF MAN."—Part XI. of "Electricity in the Service of Man," now being published by Messrs. Cassell and Co. in 15 monthly parts, is just issued, and deals with transformers, electric meters, electric motors, electric railways, and tramways. The work is very fully illustrated.

ABERDEEN.—The Gas Committee of the Town Council have resolved to recommend that the price for the supply of electricity for light to private consumers be fixed at 7d. per Board of Trade unit.

AMBLESIDE (WESTMORELAND).—The Holloway Electricity Supply Company (Limited) have informed the Local Board that they intend applying for a Provisional Order for the Ambleside district.

BELFAST.—The Corporation have, subject to evidence of title, accepted a site in Chapel-lane for an electric light station.

Digitized by Google

BRENTFORD.—The Board of Guardians have requested their Schools and House Committees to consider the question of lighting the schools and workhouse, with special reference to the possibility of introducing the electric light.

BRISTOL.—At the meeting of the Electrical Committee on Thursday last week, it was stated that owing to the non-delivery of some of the plant some slight delay would take place in connection with the general lighting of the city, although the arrangements for lighting the forthcoming Industrial Exhibition would not be interfered with. Numerous applications had been sent in for the appointments about to be made by the Committee, and the Resident Engineer was making inquiries preparatory to making final selections.

CANTERBURY.—The Town Council at their last meeting approved the recommendation of the Electric Lighting Committee that their Provisional Order, obtained in 1891, should be transferred to the Canterbury Electricity Supply Company (Limited).

CHELTENHAM.—At the meeting of the Town Council on Tuesday the recommendation of the Electric Lighting Committee that Mr. Preece's report be carried out, advising the adoption of the high-pressure alternating-current system of electric lighting for the town, was agreed to.

CHESTERFIELD.—At the last meeting of the Town Council it was reported by the Electric Lighting Committee that until replies have been received from persons residing within the "trade area" as to the quantity of electric current they would require, nothing further could be done in the matter. When these replies were received, they would be laid before the Council. The Council decided to give notice to the National Telephone Company, requiring them to remove all their poles now standing in the streets and thoroughfares, and to lay the wires underground.

FAREHAM.—It will be remembered that at a recent meeting of the Local Board the motion for adopting the contract with the Electric Lighting Company for supplying light for the streets was not carried; there were an equal number of members voting for and against, and the Chairman declined to give a casting vote. The question came up again at the meeting of the Board on Friday last, when the Clerk read the proposed contract, which had been slightly amended, the penalties for insufficient lighting being reduced from 3d. to 1½d. per hour for arc lights, and ½d. per hour for incandescent lights. Under the contract the Company agree to supply 20 arc lamps of 1,200 nominal c.p. each, and 92 incandescent lamps of 20 nominal c.p. each, for the sum of £549 per annum, for a period of three years, the contract to be terminable by six months' notice if the light did not reach the proper standard. A long discussion ensued, and the motion for passing the contract was ultimately carried by a small majority.

ECCLES.—The Electric Lighting Order, promoted by the Town Council, has received the Royal assent.

HOVE.—A Local Government Board inquiry was held at the Town Hall last week, to consider an application by the Commissioners for sanction to borrow £1,400 for the purpose of lighting by electricity the Town Hall and public offices.

ISLINGTON.—The Bill introduced for the formation of the Islington Electric Lighting Order has received the Royal assent.

KEIGHLEY.—The Town Council on Tuesday had again before them the question of electric lighting. The Gas Committee recommended that borrowing powers to the extent of £30,000 for gas works extension purposes be applied for, and, whilst the recommendation was adopted, it was stated that the Committee were carefully watching the experiments that were being made in other places with respect to the supply of the electric light.

LEAVESDEN.—The St. Pancras Parish Schools at Leavesden are to be lighted by electricity. Sufficient power for driving the dynamos can be obtained from the existing machinery.

MERTHYR.—At the last meeting of the Local Board the clerk read some letters he had received from Birmingham in regard to the cost, &c., of electric lighting, and inviting the Board to inspect the plant. It was, however, thought that installations at places nearer home would be more suitable, and the clerk was instructed to communicate with the local authority at Pontypool.

NEWCASTLE-UPON-TYNE.—The City Lighting Committee have decided to request the Watch Committee to take into consideration the advisability of taking over the electric lighting of the city generally.

OBAN.—The Caledonian Electric Supply Company (Limited) intend applying for a Provisional Order empowering them to supply electricity within the Oban district.

SHOREDITCH.—The Vestry, at their meeting last week, resumed the debate on the question of the purchase of the Pitfield-street site. After some discussion an amendment to the recommendation of the Electric Lighting Committee that a special meeting of the Vestry be called to consider the matter was carried, but a further amendment was moved that no action be taken until a financial report be made by the various bodies concerned on the scheme, and the debate on this was not finished when the Vestry adjourned.

STAFFORD.—The Town Council have adopted the recommendation of the Electric Lighting Committee to apply to the Local Government Board for permission to borrow £20,000, for the purpose of installing the electric light in the borough in accordance with the scheme prepared by Dr. John Hopkinson, who suggested the adoption of a continuous-current, low-tension system with accumulators, and the three-wire system of distribution. Dr. Hopkinson was of opinion that the electric light could be supplied at a profit with 1,500 to 2,000 lamps, and the borough engineer said that customers had already been found for 1,500 lamps at 7d. per unit.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

COMPANIES' MEETINGS AND REPORTS.

Liverpool Overhead Railway Company.

The tenth half-yearly general meeting of the proprietors of this Company was held on Wednesday, at the Law Association Rooms, Cook-street, Liverpool, Sir William B. Forwood presiding.

The Directors' report (which appeared in our last issue) and statement of accounts having been taken as read,

The CHAIRMAN said: Gentlemen, it affords your Directors very great satisfaction to meet you on this the first annual meeting after the completion of our overhead railway. This feeling of satisfaction is very much increased by the fact that the railway, both in its construction and in its electrical equipment, has been most successfully carried out. Very rarely indeed has an undertaking of such magnitude, involving so many considerations of the highest scientific importance, been so successfully inaugurated. From the first week after the railway was opened for public traffic we have maintained a regular and reliable quick service of trains; and to-day, although we are running a five minutes' service, 94 per cent. of our trains are on time, and of the remaining 6 per cent. 3 per cent. are irregular only to the extent of a few seconds. Yesterday we ran a 3½ minutes service without a hitch. For this excellent result we are indebted to the skill of our engineers, Sir Douglas Fox and Mr. Greathead, whom I am glad to see here to-day, and last, though by no means least, to the attention and care of our general manager and engineer, Mr. Cotterell. Your Directors only modestly claim credit for having insisted upon having first-class work, both in the construction and equipment of the railway, and also in having everything thoroughly and carefully tested before opening the line for traffic. The accounts presented to you to-day embrace a period of rather more than 16 weeks; we carried during that period 1,370,742 passengers, or at the rate of 4,300,000 per annum. It is estimated that the penny omnibuses at present running in competition with the railway are carrying at the rate of 2,000,000 passengers per annum, thus making the traffic already developed along the line of docks more than 6,000,000 passengers per annum; and this during a time of great commercial depression, when the shipping trade of the port has been paralysed. This depression has affected the railway in a curious way. Usually the roadway fringing the docks is so blocked with carts and lorries conveying merchandise as to make quick vehicular traffic impossible. At present the goods traffic is so light that the omnibuses have been able to make very fair running time. This, coupled with the extraordinarily fine weather, has no doubt given them a larger proportion of the passengers than will, with ordinary conditions, fall to them. We are every day developing new sources of traffic. A ride upon the Electric Overhead Railway has become an important item in the programme of every well-conducted excursion, and although our present Northern terminus is nearly a mile away from the Seaforth shore, we carry large numbers destined for Seaforth. This induces your Directors to expect a large increase of traffic on completion of the Northern extension. While we are thus engaged in endeavouring to increase the number of our travellers we are not unmindful of making such economies in our working expenses as may be practicable, having due regard to the efficiency of the service. Electrical traction, combined with automatic electric signals and lighting, should make a very cheaply-worked line; and we believe when we take the electrical generating station into our own hands we shall effect a considerable saving. But we have, however, never regretted having placed this part of our system in the hands of the Electric Construction Corporation to work for us until it had been thoroughly tested. You will notice that the result of our sixteen weeks' working has been that, after paying all expenses, rates, and taxes, and general charges, there is a balance to the credit of net revenue account of £5,361. 15s.; deducting from this interest on Debentures and the dividend due on our Preference capital we are left with a balance of £3,293. 9s. This is equal to about 2½ per cent. on our Ordinary capital for the time we have been at work. Your Directors recommend that the balance be carried forward. The amount of share capital issued is £450,000. and of Debenture stock £125,000. This your Directors estimated would complete the railway, including the Northern extension to Seaforth, but we find we have to provide about £11,000 to settle the contractor's bill of extras, and a further amount for new stations. We also consider we ought to have a sum in hand as working capital to provide for these items. We to-day, at a special meeting, intend asking you for power to issue the remainder of the Preference capital. We shall, of course, only issue such an amount as may be necessary; we are unable at present to define the amount, as a good deal depends upon the settlement of our accounts with the Dock Board. These accounts are now in course of adjustment. The Northern extension is being proceeded with, and should be completed by the end of the year. In conclusion, I have only to repeat what I have said before, that in the Overhead Railway we have a very valuable property, with a sure and, I think, rapidly progressive future. There have been many in Liverpool who have been sceptical as to the extent of our traffic, and the estimate we put forward in our prospectus of 5,000,000 passengers per annum was deemed extravagant. We have only been running for four months, yet we see a total traffic developed of over 6,000,000 per annum. It is the old, old story: give rapid, frequent, and cheap means of travel through a populous place, and you cannot fail to create an unlooked-for and unexpected amount of travel. These conditions exist on our railway, and I feel certain you will not be disappointed. No one who has witnessed the marvellous development of local travel which has followed the opening of the Overhead Railway in New York can doubt that a similar development will take place on the Liverpool Overhead Railway. We are not so fully supported by our merchants and shipowners as we had a right to expect, for the railway was mainly constructed for their convenience and to enable them to economise in their working expenses. Cotton porters, ship people, and passengers still largely use the 'buses, though the loss of time in doing so is very considerable. I think we may fairly ask the mercantile public to take a little trouble to see that their workpeople make use of the railway. We have also introduced cheap workmen's return tickets. Return tickets for 2d. are now issued up to 8 a.m., which are available for return during any hour of the day. We shall consider further concessions in this direction. We see our way to a considerable increase of our excursion traffic next year, and we are every day drawing more and more passengers from those parts of Bootle and Toxteth park in proximity to the railway. The Chairman concluded by moving the adoption of the report and the statement of accounts.

Mr. R. HOBSON seconded, and the motion was carried.

On the motion of the CHAIRMAN, seconded by Mr. R. HOBSON, a dividend of 5 per cent. per annum upon the Preference shares of the Company was declared.

This concluded the business of the ordinary meeting, and it was now resolved into a special one according to notice given.

The CHAIRMAN said the object had already been explained to them, and he simply moved:—

"*That the Directors be and they are hereby authorised to issue four thousand five hundred Preference shares of £10 each (being the unissued portion of the twelve thousand Preference shares of £10 each, bearing interest at the rate of £5 per centum per annum, created by the Company on January 10, 1893) in such amounts and manner, at such times and on such terms, as they may think fit.*"

Mr. HOBSON seconded, and the resolution was carried unanimously.

Mr. STEVENSON, a shareholder, inquired when it was intended to extend the railway southward.

The CHAIRMAN said they had parliamentary powers to carry the line southward, so as to effect a junction with the Cheshire Lines Railway, and if they exercised these powers they would tap a large traffic. They had pledged themselves to the shareholders that they would obtain their sanction before proceeding with the extension, and that pledge they would carry out. At present the Directors thought that it would be better for them to develop the present line before fully undertaking that extension.

Another SHAREHOLDER asked if it was the intention of the Directors to allot the new issue of Preference stock among the Ordinary shareholders.

The CHAIRMAN said the subject would be carefully considered by the Board, and he hoped that the Ordinary shareholders would obtain the bulk of the new stock.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

Oxford Electric Company (Limited).

The ordinary general meeting of the shareholders of this Company was held on Friday at the offices, 45, Broad-street, Oxford.

The CHAIRMAN (Sir Henry Mance, C.I.E.), in moving the adoption of the report and accounts for the last year, said: Since we have commenced work the Directors have been aiming to effect three things—first, to increase the revenue; secondly, to decrease the expenses; and, thirdly, to render the system by which we generate and supply current as economical and perfect as possible. With regard to revenue, although that for the first week was less than one sovereign, it steadily increased during the six months, the best week's receipts being £86. The number of customers has increased to 70, that is, counting the colleges as one only, notwithstanding some of them have several hundred lights. We have at

Digitized by Google

present an equivalent of 5,060 8 c.p. lamps installed. With regard to reduction in expenses, we have thought it desirable to remove the management from London. Mr. George Offor, our late manager, had been associated with this Company from its inception, and although he is now devoting himself to the development of the Crystal Palace District Electric Supply Company, I am quite sure that if we required his good offices again his friendly services would always be at our disposal. No one can appreciate more than I do the value of work which invariably has to be carried out in connection with the formation of a company of this kind, and I ought not to allow this opportunity to pass without expressing my thanks to Mr. Offor. It was, however, felt that when once fairly launched the management of the Oxford Company might safely be left to local staff. Mr. J. H. McLean has been appointed our engineer in charge, and Mr. H. Eeles our local secretary. We have ceased to pay rent for our London office, and these changes have resulted in considerable economy, without, I may say, impairing efficiency. With regard to our system, which I believe is worked with fewer interruptions or fewer difficulties than any installation of similar size in the country, we have been able, by the use of a supplementary transformer, to charge our batteries with much greater economy. We have also introduced improvements in the automatic switch used at the sub-stations, and Mr. McLean has designed a very ingenious apparatus which, suspended inside the arc light lamp-post, puts out the lamps at any required hour, thus dispensing with the necessity for sending an attendant round during the night. On December 31st the length of trench work done amounted to about 6,500 yards, containing 12,000 yards of Callender's low-tension mains, and 10,500 yards of the Silvertown high-tension india-rubber cables. The whole of this is in as perfect order as when laid. With regard to future prospects, the engineer in his last report anticipated that by the beginning of October we should have an additional 2,000 lights. The Directors have under consideration the introduction of a sliding scale of charges, which will lessen the cost of current and benefit not only the large consumers, but those who, having only a small number of lights, use them continuously.

Ald. BUCKELL, having seconded the proposition, the report and balance-sheet were unanimously adopted.

Mr. W. S. Carver was then appointed auditor, and the proceedings terminated.

Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30th, to be presented at the forty-fourth ordinary general meeting of shareholders, to be held at the Company's offices, 58, Old Broad-street, E.C., on Wednesday next, at 12 noon :—

The gross receipts for the half-year (including the balance brought from last account) amount to £25,151. 15s. 11d., and the gross expenditure to £6,749. 8s. 5d., leaving a sum of £18,402. 7s. 6d. to the credit of revenue account. Of this the sum of £1,500 has been set aside as a reserve against any loss from the deposits with banks, and £5,500 added to the reserve fund, making that fund £100,000. The dividend on the Preference shares will absorb £3,000, and leave £8,402. 7s. 6d., out of which the Directors recommend the payment of a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £2,002. 7s. 6d., being carried forward to the current half-year's account. In view of the probable reduction of rates at no very distant date, the Board has determined to carry forward a larger balance than usual, towards meeting any diminution of the net income during the earlier period of the change.

The main cables have continued in good order throughout the half-year, with the exception of the Batabano-Cienfuegos 1870 cable, which underwent some repairs in March. The cost of these and of the New Harbour lengths, referred to in the last report, appear in the present accounts.

No decision has yet been given in the Company's suit against the Spanish Government at Madrid, but efforts are being made to bring the case to a conclusion.

The Director who retires from the Board at this time is Mr. George Keith, who, being eligible, offers himself for re-election. Mr. John Gane, the auditor, also retires, and is eligible for re-election.

Birmingham Central Tramways Company (Limited).

The report of the Directors of this Company, which is to be submitted at the meeting to be held at the Queen's Hotel, Birmingham, on Wednesday, the 16th inst., at 12:30 o'clock, states that the decrease of working expenses and increase of working profits is shown in the following comparative statement :—

Year ended June 30	Miles run.	Passengers carried.	Traffic receipts, &c.	Working expenses.	Working profits.
			£ s. d.	£ s. d.	£ s. d.
1892...	2,657,145	25,718,282	152,238 15 2	116,210 13 5	37,028 1 9
1893...	2,655,802	26,277,089	154,684 5 3	111,230 4 10	43,454 0 10

The revenue account shows a balance of £24,216. 8s. 1d., which, with £13,921. 18s. 8d. brought forward, makes £38,138. 6s. 9d. The Directors recommend—

(1) That £20,000 be placed to reserve account against depreciation.

(2) That the payment of the dividend on the Five per Cent. Guaranteed shares, amounting to £5,000, be confirmed.

(3) That a dividend of 2½ per cent. for the year ending June 30th be declared on the Ordinary shares, amounting to £9,700 ; and

(4) That the balance of £3,438. 6s. 9d. be carried forward.

The balance of £9,302. 18s. 4d. due to the bankers on June 30, 1892, has been repaid, and on June 30, 1893, the bankers held the sum of £8,623. 9s. 5d. to the credit of the Company. The auditors' special certificate states that the Company have Debentures to the amount of £18,000 available for issue, and that the reserve fund is invested in the most legitimate manner in the development of the resources of the Company.

The present Directors retire, and offer themselves for re-election. Messrs. B. J. Round and J. Booth, of Birmingham, substantial shareholders in this Company, submit themselves as additional Directors. The present Directors trust that the nomination of these very representative shareholders may be cordially supported. Upon the representation that his retirement at the present time would be detrimental to the interest of the Company, Mr. Ebbsmith submits himself for election as a Director for the ensuing year, on condition that he will be permitted to retire from the chair. The auditors (Messrs. Howard Smith, Slocombe, and Co.) retire, and seek re-election as auditors of the Company.

The working accounts for the twelve months accompany the Directors' report. The tramways are worked by steam, horses, cable, and electricity, and the receipts for the electrical cars show a small loss of rather less than £100. The total miles run by the electrical cars for the period was 140,993, and the passengers carried 1,257,399.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

LANE FOX ELECTRICAL COMPANY (LIMITED).—Mr. St. George Lane Fox, the Chairman of the Directors, notifies the Registrar of Joint-Stock Companies that there have been no transactions of any kind to record, and the Company has practically ceased to exist and will shortly be wound up in proper form, as the purposes for which it was registered were not proceeded with. Nothing whatever has been called on any of the shares, and no property has been transferred to the Company.

LONDON AND LANCASHIRE ELECTRIC AND GENERAL ENGINEERING COMPANY (LIMITED).—The statutory return of this Company, made up to July 11th, has been filed. The nominal capital is £20,000, in £5 shares, of which 1,786 have been taken up. 1,000 shares have been issued as fully paid while £2 per share has been called and paid on the remaining 786 shares, resulting in the payment of £1,146, and leaving £426 in arrears.

CITY NOTES, &c.

CALLS DUE.—*August* 15 : CITY OF LONDON ELECTRIC LIGHTING COMPANY, £3 per share on £20.000 Six per Cent. Cumulative Preference £10 shares (this sum includes £1 per share premium) ; ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY, 25 per cent. on £5,000 Ten per Cent. First Mortgage Debenture stock.——*August* 31 : NATIONAL TELEPHONE COMPANY, £25 on £273,523 Four and a-Half per Cent. Debenture stock.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended August 6th were £801, as against £919 for the corresponding period of last year, being a decrease of £118. The total receipts for the half-year amount to £4,226, against £3,940 in the corresponding period of 1892, being an increase of £286.

DIRECT SPANISH TELEGRAPH COMPANY.—The gross receipts for the month of July were £1,656, as compared with £1,684 for the corresponding period of last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for July amounted to £24,000, and from January 1st to July 31st to £156,800. In the corresponding months of 1891 and 1892 the amounts were £152,000 and £165,800 respectively.

SALT LAKE AND OGDEN GAS AND ELECTRIC LIGHT COMPANY (LIMITED).—A prospectus is issued of this Company, which, under the auspices of the Gas, Water, and General Investment Trust (Limited), offers for subscription $1,250,000 Six per Cent. First Mortgage Bonds at £205 per $1,000 bond, payable £20 on application and £185 on allotment. The Company is incorporated under the laws of Utah, U.S.A. It is difficult to understand why subscriptions are invited from the British public, as hitherto the management of the concern appears to have been in American hands ; but (the prospectus states) to secure continued efficient management of the properties, an English Company has been formed in which the control of the American Company will be vested, and the Directors of this English Company are Directors of the Gas, Water, and General Investment Trust (Limited). The English market will probably find other outlets for its superfluous capital. There are many electrical undertakings at home languishing for financial support, several of which appear much more likely to result satisfactorily. The list of applications closes on Saturday, the 12th inst., for London, and Monday, the 14th, for the country.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended August 4, 1893, after deducting 17 per cent. of the gross receipts, payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,984.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the two weeks ended July 31st were £1,778, as compared with £2,023 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 796.—Vol. XXXI. FRIDAY, AUGUST 18, 1893. PRICE FOURPENCE.
Annual Subscription (U.K.), 19/6

NOTES.

We have received a report of the interview between the Gas and Electricity Supply Committee of the Bradford Town Council and Lord Kelvin. As was stated in a note four weeks ago, the time has come when an extension of the municipal supply in this town is necessary, and the Corporation having become aware that their two-wire system was quite antiquated, have received reports from Mr. Shoolbred, who to show that he was quite up to date suggested a five-wire scheme with automatic contrivances at the ends of the feeders for maintaining a constant voltage, and another from their engineer, Mr. Baynes, to whom so much credit is due for the success of the undertaking, and who is well competent to advise on the case. As these reports to some extent conflicted, Lord Kelvin was asked to adjudicate thereon. Some men would have given an opinion as a Q.C. would do, without rising from his chair after perusing the documents. Not so Lord Kelvin. He visited Bradford, examined the works, investigated the probable requirements of the town, and attended a meeting at which both Mr. Shoolbred and Mr. Baynes were present, and submitted to a volley of questions for about three hours. No higher tribute could be paid to his versatility than the variety of the questions which it was thought suitable to put to him. The comparative merits were discussed of two, three, and five wires; of Willans and Corliss; of accumulators and gas engines; of 180lb. steam or 140lb.; boilers upstairs or downstairs; Lancashire or Babcock-Wilcox; cables or culverts; the propensities of Bradford rats; "if we get 90 per cent. of energy from the dynamos, where does the other 10 per cent. go to?" To all these and many further questions Lord Kelvin gave ready and simple replies, and, had time permitted, he would no doubt have advised with equal gravity as to whether brown or green would be the best colour for the office door. The interview was closed by the following important question and profound reply: "Councillor L. Walker asked Lord Kelvin how long he thought the extensions would take to complete them, that is, the extension now in progress? Lord Kelvin could not say, as much would depend on the builder, and otherwise, but he hoped they would be finished in good time for the winter requirements." It is a great pity that someone did not ask for Lord Kelvin's views as to the rate of propagation of gravitation; it would all have come into the day's work, and the ratepayers could hardly have objected.

The Technical Education Board of the London County Council has published the conditions under which it is prepared to grant aid to the carrying on of evening science classes. Careful thought and a considerable amount of experience of the virtues and vices of science classes is exhibited in the schedule. In one respect particularly the Board is to be commended, namely, in its decision to afford no assistance whatever to classes which are "farmed" by the teachers, or in which the system of payment by results is practised. This viciously inefficient system deserves to have the full weight of all constituted authority against it. In regard to the experimental sciences, the Board is no less careful that its aid shall flow into proper channels; for it stipulates that provision shall be made, "not only for the experimental illustration of the lectures or class teaching, but for experimental work by the students themselves," and that "every lecture must be followed by at least one hour's practical work on the same evening or some other evening in the same week."

Another important element of true instruction which it is sought by the Board to foster is the practice of setting "home work." This is stipulated in connection with the mathematical and geometrical subjects, and is a most satisfactory proviso. The mere attendance at lectures, necessary though it is for acquiring a head knowledge of these subjects, is of little or no use in imparting that facility and skill in the practice of them without which they are of no technical value. A number of small scholarships will be awarded by the Board some time next November. Not more than 100 of these will be awarded to boys, and not more than 100 to girls; and the value of the scholarship will include free education at such schools as the Board may approve, and a money payment of £8 during the first and £12 during the second year of tenure.

Some observations are made in *Industries and Iron* on the waste of work at those technical colleges in which students are put to original research by way of instruction; and some good suggestions are made as to researches which are well worth carrying out, but which engineers have no time to follow up at their works. One of the best and most simple of these suggestions is the following:—

The carrying capacity and resistances of hot wires for use as rheostats for large powers are also well worthy of investigation. If iron is used there is an uncertainty about the temperature coefficient, and the specific resistance, so that it is difficult to know beforehand what a given set of spirals will do. If a more expensive metal or alloy is used what is wanted

Digitized by Google

is to get the largest surface with the least metal; that is to say, the wires should be as thin as is compatible with mechanical strength and durability. This is often overlooked, and resistances for large currents are made of large wire, whereas several small wires in parallel would be cheaper. The information wanted is the carrying capacity of spirals of different pitches and diameters, of wires of different gauges of copper, and various definite alloys. Another form of resistance is very convenient. It consists of strips of iron, lead, or other metal immersed in water. This form is cheap to make, and very convenient; but information is again required as to the carrying capacity of various wires under water. Here is some more work for technical colleges.

It is, however, easier to make the suggestion, than to induce ambitious students to relinquish "the measurement of simple resistances by the five-split dynamometer method; the critical state of hypothetical dynamos run at half-speed with double load." We shall be very glad to receive from our readers any notes about the carrying capacities of spirals of different pitches and diameters, and of strips of metal in water, and would collect and reduce their observations to some general rules for the construction of such resistances. It would always be open to the college experimenters to show that owing to suppressing the variation of g with the latitude, or some such error, everybody else's results were wrong.

We publish this week two articles which we flatter ourselves are of a peculiarly seasonable character, relating as they do to lightning. The notes sent us by Mr. Doran serve mainly to show once more what lightning can do when put to it, but since it is only from the laborious collection and collocation of accurate data of this kind that the next advance towards a satisfactory theory of lightning and lightning protection can be looked for, the account in question may perhaps be of some use to our future generaliser. In the experiments of M. Massin we have an attempt, not indeed to secure a unit lightning flash, but to secure a unit lightning guard in the shape of a certain plate protector; the behaviour of other types being expressed in terms of the air-gap that it is necessary to give the standard protector in order to secure a balance in the Wheatstone Bridge arrangement adopted. In addition to reproducing the average practical conditions as near as may be without the dangerous collaboration of a good thunderstorm, M. Massin's method of testing the relative effectiveness of plate, comb, and mica-sheet protectors seems likely to lead to sound conclusions as to their relative effectiveness. M. Massin certainly condemns the mica protector, but as he apparently used a solid sheet of talc instead of the perforated sheet adopted in the British Post Office pattern, his condemnation does not necessarily mean that either his experimental methods lead to erroneous conclusions or that the Post Office pattern is all wrong.

We hear that a unit of earthquake has been decided upon and adopted in a Paper recently read before the Royal Society, so that the magnitude of a seismic convulsion can now be scientifically expressed to any number of decimal places. To be quite scientific, however, the C.G.S. system should be used, and the earthquake should be expressed in terms of length, mass, and time and all the suppressed dimensions. Omitting these latter, the C.G.S. unit of earthquake might be defined as that amount of quake which, acting on a gramme mass of the earth's crust with a frequency of one harmonic vibration per second, would cause it to heave up and down with an amplitude which would increase at the rate of one centimetre per second. Then the unit should have a name—that of some famous defunct seismographer would probably be the most serviceable; and there should be a huge "practical" unit, and a microscopic "absolute" unit connected together by 10 to no end of powers. But perhaps the unit selected is not "scientific"—only convenient.

The Compagnie Edison.—This concern is stated to be contemplating adopting Brown apparatus in its future undertakings.

Free Technical Education.—A gratuitous course of lectures in electricity has been inaugurated at the Maison des Ouvriers, in Brussels, under the direction of M. Buse, jun.

The International Electrical Congress.—It is stated that the Congress Committee on Invitations has issued nearly 950 individual invitations. It is expected that the attendance will amount to not less than 500.

Chicago Exhibition.—Information has been received that the judges have at last got to work. Amongst the British judges, we note the names of Profs. Ayrton and Forbes (Electricity), Prof. W. Cawthorne Unwin (Machinery), and Prof. Silvanus Thompson (Instruments of Precision: Liberal Arts).

The City and South London Railway.—The passengers on the down line of the City and South London Electric Railway were inconvenienced on Tuesday evening last by the bursting of the hydraulic main at the Oval Station. Before the supply could be turned off the water had partially flooded the line, and it was with great difficulty that the trains could proceed.

Fire Prevention and Extinction.—A gold medal of the value of 1,000 lire is offered by the Royal Academy of Science of the Institute of Bologna to the author of the best memoir describing a new and efficacious system, or a new apparatus, for preventing or extinguishing fires. The memoir may be written in Italian, Latin, or French, and must be sent in before May 7, 1894.

Underground Telephone Wires.—In reply to a question in the House of Commons last week, the Postmaster-General stated that the powers to place telephone wires or tubes underground either in London or other towns were regulated by statute, and were in all cases subject to the consent of the Local Authorities, with an appeal in certain cases to a police or stipendiary magistrate or county court judge, and a further appeal to the Railway Commissioners.

Earthing Alarum.—The *Electrical World* describes a novel form of fault detector, consisting of a modified form of electric bell. The device is intended for use with storage batteries. When a fault puts the line to earth for more than a prearranged time—which can be varied from one to 20 seconds—the bell rings. While the bell is ringing its resistance and back electromotive force are such that the leakage current is cut down to a very low figure.

Photographing Flying Bullets.—E. and L. Mach, who have done a considerable amount of work in connection with the photography of flying bullets, air jets, and sound waves, recently communicated the results gleaned from a series of about 1,500 negatives to the Vienna Academy. Sharp images of Mannlicher rifle bullets were obtained of 3·5cm. diameter. The experimenters closed the spark circuit mechanically by means of the sound wave produced by the bullet itself.

Coventry.—At the quarterly meeting of the Town Council on Tuesday last the report of the Electric Light Committee recommending that the Corporation undertake the supply of electrical energy under the Provisional Order, that the high-pressure, alternating-transformer system be adopted for private lighting, and that street lighting be not at present undertaken, that a site be purchased in Sandy-lane, and that a consulting engineer be employed to advise the Committee upon the selected specifications and estimates was adopted.

Digitized by Google

Lord Kelvin.—The August number of the *Review of Reviews* contains for its usual character sketch an article on Lord Kelvin from the pen of Mr. J. Munro. A very interesting *résumé* of the salient points in the life of Lord Kelvin, whom the writer styles the Napoleon of Natural Philosophy, and of his principal conquests in the domain of science, is to be found in this article, which electricians will no doubt find to be instructive and pleasant reading. The article is accompanied by several portraits of Lord Kelvin, and views of his residence and of Glasgow University.

The Kashmir Telegraph Line.—Good progress, says the *Indian Engineer*, continues to be made in laying the new permanent telegraph line between Srinagar and Gilgit, and the work will be completed by the end of September. It is intended to maintain two posts of observation between the Passes during the winter months, so that breaks due to the snow or avalanches may be rapidly repaired. As these posts will be completely cut off from the outside world for many months, they will be fully provisioned, and parties of picked men only will be stationed at them.

Naval Electric Signal Lamp.—Advantage has been taken of the naval manœuvres, says the *Army and Navy Gazette*, to compare a new electric masthead flashing lamp, submitted by Sir Wm. Armstrong and Co., with the service pattern lamp. In the former the light is enclosed by a number of shutters, which are caused to open or shut, in the latter the operator switches on and off the lamp. On board the "Royal Sovereign" one lamp was placed at the foremast head, and the other kind at the main, and signals made with them. The Fleet were unanimously in favour of the shutter lamp, on account of its sharpness and clear definition of the long and short flashes.

Wild Horses and Electric Eels.—It seems that Humboldt, like the too credulous Herodotus, must have been "taken in by a native" when he heard and put on record the story about the capture of electric eels in South America by driving wild horses into the pools where these seats of electromotive force are to be found. It appears that a writer in the *Spectator* who has travelled on the llanos of Caracas — where Humboldt heard the story—has been making inquiries himself, and has failed to find any confirmation of this method of capture; but that, on the contrary, these *trembladores*—as the eels are called—are caught in the most prosaic manner by means of nets and a lineman's india-rubber gloves.

The Cushman Dynamo.—One of the most novel features in this dynamo, which has recently been put on the market by the Granite State Electrical Company, Concord (N.H.), is the manner in which a well-balanced field is obtained at the polar surfaces. The field-magnets are of the well-known horseshoe vertical pattern; but instead of being bedded directly on to the frame they are supported on two short electromagnets, which are wound similarly to a double magnet dynamo. The carcase is, in fact, a double magnet in which one magnet—the upper one—is much longer and has more windings than the other. By this means heating at the bearings and other defects arising from want of magnetic balance are avoided.

The Gas Light and Coke Company.—The *Gas World* calls upon Mr. Preece and "other enthusiastic electricians" to witness its joy over the fact that, making allowance for all changes in price, the Gas Light and Coke Company's rental "in the very headquarters of electric lighting"—the West End—has gone up some 10 per cent. in three years. But, wherefore call on the electricians? The fact of there being such a headquarter of electric lighting only proves that gas has not got things all its own way; and the fact that the gas industry has improved 10 per cent. only means that more gas stoves and gas engines are in use. We are not surprised at the increase in the gas consumption; we are very glad of it; we expect to see another 10 per cent. in the next three years.

Trolley Boats.—A party of capitalists, says *Electricity* of Chicago, said to have some connection with the Santa Fé Railroad system, has been visiting the Grand Canyon of the Colorado River for the purpose of investigating the feasibility of laying an electric cable 500 miles in length along the river with which to drive small boats up through the Black Canyon and other scenic points, where the cliffs, over a mile in height, overhang the stream. Power is to be generated by water-wheels driven by the current of the river itself, or, wherever feasible, the water will be diverted into canals. A copper wire cable will be suspended over the centre of the river, which is, for the most part, about 300ft. in width, and electric power will be conveyed to small steamers as in the case of electric railways.

Worcester—At a meeting of the Town Council on Tuesday last the Mayor proposed the adoption of the recommendation of the Watch Committee to adhere to the original proposal to construct a generating station at Powick, on the banks of the Teme, for electric lighting purposes, and that the tender of Mr. Thomas Rowbotham, of Coventry-road, Birmingham, to construct the station at a cost of £14,797, be accepted. The City Chamberlain proposed an amendment to the effect that the Committee proceed to construct a generating station in Worcester at a cost not exceeding £20,000. On being put, 10 voted for the amendment and 22 against it. The original motion was then put and carried. Mr. W. H. Preece was appointed consulting engineer, and Mr. Leonard Wigan was appointed clerk of the works.

Measurement of the Resistance of the Human Body.—While engaged on some measurements on the electrical resistance of the human body M. Mergier was led to the construction of a simple instrument on the Evershed ohmmeter principle capable of making such a measurement with accuracy. The instrument consists of two coils of insulated wire, fixed with their planes at right angles to each other, and placed within the field of a strong horse-shoe magnet. These two coils are connected in series with the resistances to be compared, and to the terminals of a battery. Under these circumstances, the position of equilibrium of the coils depends only on the ratio of the resistances of the two branches (coil and added resistance), and is independent of the value of the electromotive force of the battery.

Telephone Subscribers' Agitation at Rotherham.—A meeting of the Rotherham subscribers to the service of the National Telephone Company was held last week. The Company, it seems, has given notice to increase the rental from £5 to £8 per annum. After discussion, the meeting expressed itself in favour of the present rate, or the alternative course of dispensing with the service. A very general feeling was manifested in the direction of an improvement of the service, and complaints were made of want of attention at "The Central," and of difficulty in telephoning with Sheffield and outside districts. It was decided to communicate the views of the meeting to the Manager. It was announced that there were 126 subscribers in Rotherham, and that more than one-third of this number had given their opinion on the proposed charges.

A Municipal Tax on Electricity.—A very curious question, says *La Lumière Electrique*, has recently been disposed of by the civil tribunal at Vigan. This town had rented out its municipal taxes to a M. Carrière, and among the dutiable articles over which this gentlemen thus acquired control were petroleum and candles. In course of time the municipal authorities gave their sanction to an electric lighting scheme, and permitted the new mode of illumination to go untaxed. The result was a certain falling off in M. Carrière's revenue, owing to the lessened consumption of candles and oil. M. Carrière naturally made complaint to the civil authorities, who accorded him damages to the amount of 400fr., and decided to hold the electric light company responsible to the municipality in respect of any further injury to the taxation.

Bradford.—At the meeting of the Town Council on Tuesday last, Alderman F. Priestman (Chairman of the Gas and Electricity Committee), in moving the adoption of the minutes of that committee, gave his half-yearly statement. In the electric lighting department he said that the sales up to the end of June 30, 1893, were £4,210, against £3,126, and the gross profit for the half-year was £2,293, against £1,673, whilst the net profit was £625. 16s., against £387. 7s. for the corresponding period. The total expenditure on the electricity works was £62,109, and there was a profit balance on the whole of the working of £915. 12s. 6d. He also included in his motion a

Digitized by Google

recommendation that the necessary work required in connection with the application of the "three-wire" system, at an estimated cost of £2,020, be proceeded with; and that the Council accept the tender of Messrs. Siemens for the supplying and fixing of two engines, with dynamos, and two switchboards, for the sum of £3,025. The motion was carried unanimously. It was also agreed to pay the Westinghouse Company £2. 10s. per annum per ton of copper actually laid down for the use of the Hopkinson three-wire patent.

Electrical Resistance of Thin Liquid Films.—In a Paper recently read before the Royal Society by Profs. Reinold and Rucker, "On the Thickness and Electrical Resistance of Thin Liquid Films," the authors have shown that a discrepancy arises between the results when the thickness of a film is measured optically and when it is measured electrically on the assumption of a constant specific resistance. The discrepancy is such as to indicate that, in general, the specific resistance of the film falls as the thickness is reduced. The Paper concludes with a discussion as to the cause of the increase of electrical conductivity of thin films. The authors point out that it may be attributed either to a modification of the chemical constitution of the film, brought about by its tenuity, or to the formation of a pellicle on the surface. They prove that the experimental results cannot be explained by the formation of the pellicle only, but that they are consistent either with the former or with a combination of both causes. To discriminate between them it will be necessary to carry out observations in gases other than air, and an apparatus specially designed for this purpose is being constructed.

Damage by Lightning.—The following list is interesting, as showing some of the damage by the thunderstorms of Thursday last week:—

Helensburgh	Farmhouse struck; telephones damaged.
Devizes	Belfry demolished.
Lynn	Oat stack fired and destroyed.
Heywood	Mill damaged.
Bakewell	Farmhouse struck.
Melton Mowbray	Horses injured.
Shillingford	Nine beasts killed.
Belfast	Mill fired.
Near Omagh	Belfry destroyed.
Banagher	Church struck; cattle killed.
Near March	Horse and man killed.
Ballymarlow	Flax mill burnt.
Boston	Stack of wheat fired.
Dunmow	Farm struck.
Folkestone	Two houses struck.
Ashby-de-la-Zouch	Cattle killed.
Great Coggeshall	Church tower destroyed.
Sheffield	Chapel struck.
Alderton	Woman killed.
West Mersea	Chimney struck.
Holyhead	Man killed.

In Paris a house was fired. Within a hundred yards of this a woman who happened to be passing along the street with a baby in her arms was killed, together with the infant. A similar occurrence took place at Cappelle, where a woman who was leading a child was killed, the child being rendered unconscious. At Doudlens two men were killed.

The Mende Central Station.—The Mende central station, which was started in 1888 was, says *L'Industrie Electrique*, laid down as a steam-power station, the plant comprising two high-speed engines of 120 H.P. each coupled direct to 75 kilowatt dynamos. As, however, the maximum output never rose above 45 kilowatts financial considerations rendered a reorganisation of the station necessary, and a waterfall being available about two miles outside the town it was decided to make use of it, but as it gave only 35 H.P. in summer storage batteries were necessary, and to keep the number of these down as much as possible the following intricate device was resorted to. The shunt-wound 800-volt generator at the fall supplies current to a 600-volt motor, driving a 105-volt 250-ampere dynamo feeding the lamp circuit. In parallel with the lamps is a series-wound motor coupled to a small dynamo. The field of this dynamo is double-wound, one set of coils forming part of the motor circuit, the other being taken off the omnibus bars. During the hours of light load this auxiliary machine gives 200 amperes, and adding 30 volts to the 105 volts on the lamp-circuit charges the accumulators. As lamps are switched on the current in the motor circuit winding diminishes, reducing the electromotive force of the auxiliary machine to 5 or 10 volts; the poles are then reversed and these 5 or 10 volts are added to the battery which then discharges through the lamps. As a 60 H.P. steam-engine is kept as a stand-by it is somewhat difficult to realise the value of a waterfall entailing so much complication.

The Absorption of Light by Platinum.—Dr. G. B. Rizzo has constructed an ingenious piece of apparatus, recently shown at the Accademia delle Scienze di Torino, for obtaining thin films of platinum on glass by electric volatilisation. The difficulty hitherto experienced in the investigation of the change of transparency of thin metallic films with the temperature has been to keep the films from oxidising. Dr. Rizzo's apparatus consists of two glass cylinders joined by a thin tube soldered in a T-joint to another leading to an air-pump and a reservoir of nitrogen. Both the cylinders contain platinum electrodes, one of which is sheathed in glass along half its length. By repeated filling, the composite tube is made to contain a rarefied atmosphere of nitrogen. On connecting the glass-sheathed electrode to the negative pole of an induction coil, worked by six Bunsens, and making circuit, the unprotected half of the electrode is rapidly volatilised and deposited in a thin even film on the walls of the cylinder. Nitrogen is then allowed to enter up to atmospheric pressure, and the cylinder containing the film is melted off. The electrode is bent out of the way by softening the junction of its glass sheath, and the cylinder is mounted in a small furnace heated by a spiral tube of gas jets and provided with windows. To determine the transparency at various temperatures, light is sent through the walls of the cylinder near the edge of the film, and the intensities of the various wave-lengths transmitted outside and inside the edge of the film are measured by the spectro-photometer. Dr. Rizzo found that the transparency of platinum increased with the temperature, especially in the more refrangible region. According to the electromagnetic theory of light, both the resistance and the transparency of a conductor should increase, and the resistance and transparency of a dielectric should diminish with a rise of temperature. As far as these experiments go, therefore, their results are in perfect agreement with this theory.

Electrical Markets in Spain.—English electrical firms, writes a correspondent, ought to begin to think of the Spanish markets. It does not by any means do honour to the proverbial British enterprise to see how such an important and accessible field is being left almost entirely in the hands of German and French firms. Very little seems to be done to bring before the notice of the Spanish public what we can do. The numerous Spanish technical publications are crammed with advertisements of foreign firms, but the names of British houses are conspicuous by their absence, the only one which seemed to show some interest in this respect having now disappeared from the Spanish arena on account of financial difficulties at home. I have seen an illustrated catalogue published in Barcelona. It contains cuts of several dynamos of the Brush type, and other appliances of English make, and, although the descriptions are given in rather bad Spanish, the get-up is very practical, having a decided advantage over most trade catalogues issued in England, *i.e.*, the quotations are given in Spanish money, and the measurements according to the metric system. Unfortunately, the most important English concern in Spain, the Electricity Supply Company for Spain, is hardly yet a success, for the balance-sheet, which was not published in the *Gaceta* until May 19th last, dated the 14th of the same month, showed a deficit, referring to which the *Revista Minera*, of Madrid, says: "In our opinion, to lose this money is far more clever than gaining it, considering the great demand the electric light has always met with here, and the relatively small competition the Company has had to face." A good opportunity for English engineers and manufacturers to study the Spanish markets and vindicate their prestige will be the forthcoming International Exhibition at Madrid, which is to be held at the Palace of Arts and Manufactures from May 1 to October 31, 1894. The exhibits are to be distributed in fourteen groups, one of them being "Electricity."

THE SMYTHE-PAYNE SYSTEM OF FIREPROOF WIRING.

The premises of Messrs. J. and B. Stevenson's restaurants, and other business houses in the City, have recently been wired for the electric light on a fireproof system invented and carried out by Messrs. Smythe and Payne.

The essential features in this system, which we described at its first inception, consist in the use of bare copper conductors, and of insulating and protecting materials, which are incombustible nnd imperishable under ordinary conditions. These features are arrived at in a great variety of ways, which, though the general character of them all is the same, are severally suited to different classes of work. Thus, for some purposes a pair of concentric tubes, composed of rolled copper, separated by porcelain rings placed at frequent intervals, and protected by being placed inside an iron, brass

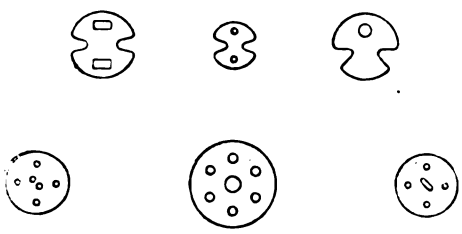

Fig. 1.—Smythe and Payne System of Wiring. Porcelain Separators.

or other metal tube, is used. On other occasions the conductors are composed of bare wires or thin strips of tinned copper, which are threaded through porcelain insulating separators of various shapes, some of which are shown in Fig. 1, the whole being drawn through either rigid or flexible metal tubing, to serve as a mechanical and water-proof protection, according to requirements.

The details of the system appear to have been very completely worked out; for suitable forms of switches, fuses, lamp attachments, &c., have been designed for use with the tubular wiring; and the difficulties met with in going round bends and making curves in the wiring have been boldly attacked. One method of wiring at a bend, which is used in the premises we have named, is illustrated in Fig. 2. Here there are three bare copper wires, which on each of the straight lengths that meet at the bend are carried in metal tubes, and separated by porcelain insulators. These insulators are of a circular or disc-

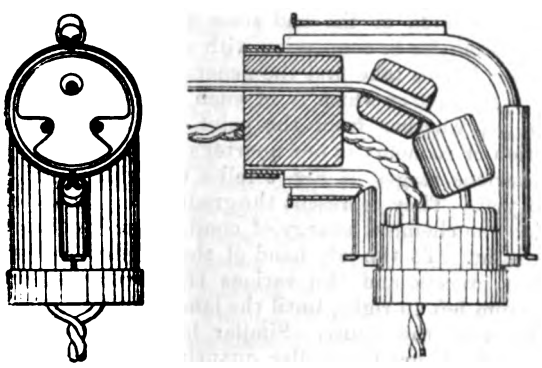

Fig. 2.—Smythe and Payne System of Wiring. A Bend.

shaped form, with two deep indentations for carrying two of the wires, and with an eccentric hole, through which the other wire is passed. Between the porcelain insulators the two wires, which are laid in the indentations, are twisted together into one conductor, whereby the insulators are prevented from movement along the wire. The bend in the outer tube consists of two bent semi-cylinders, the edges of which are flanged. These are stamped in sheet brass, and are placed with their flanges abutting so as to form a tube round the conductors. The ends of this brass tube lap over the ends of the straight lengths of metal tubing and are clamped to them by means of a couple of rings. The flanges are secured by means of a channel key which is slid over them; and all the seams are made secure and watertight with solder. Contact between the bare wire and the metal tube is prevented, at the bend, by means of a couple of porcelain rings, which are threaded on to the wire as shown in the illustration.

Another mode of making a bend in the wiring is shown in Fig. 3. In this the two outer pipes which are coupled together are effectively insulated from one another, so that a contact between a conductor and any section of pipe cannot establish an earth through the whole system of pipes. The coupler consists of two porcelain angle-pieces, provided with

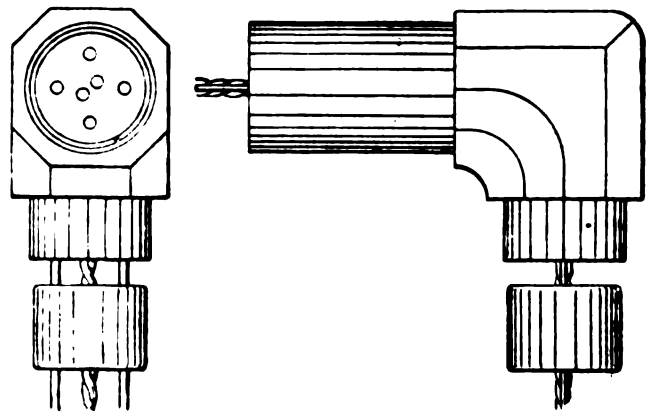

Fig. 3.—Smythe and Payne System of Wiring. A Bend.

circular plugs, which can be fitted into the two tubes. At the surface of contact between these angle-pieces, which is indicated by the curved line in Fig. 3, there are a number of grooves or channels which form separate conduits for the isolated bare wires and effectively insulate them. It will be noticed that in

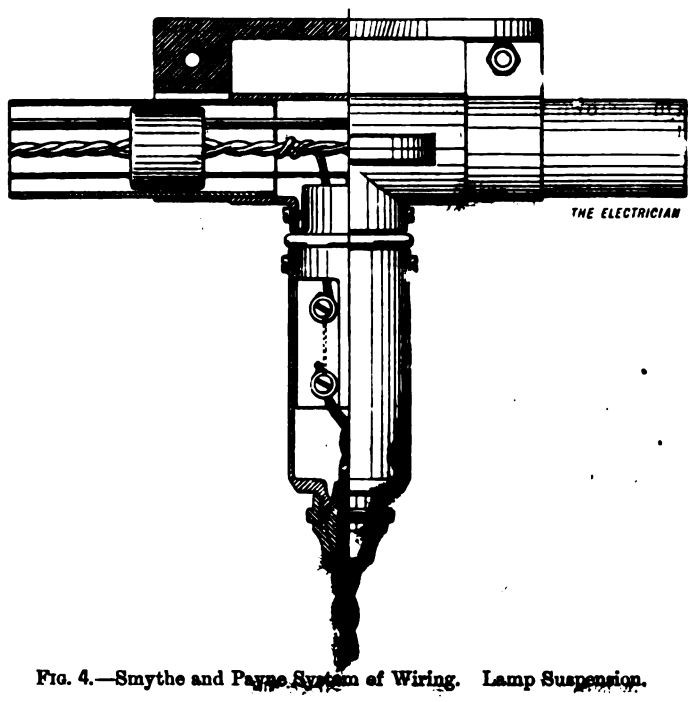

Fig. 4.—Smythe and Payne System of Wiring. Lamp Suspension.

the illustration there are holes in the circular separator for six wires, namely, for two near the centre, which would be twisted together, similarly to those in Fig. 2, and for four others which would be isolated from one another and drawn straight through the system of tubing. The advantages claimed for this practice are that it very much reduces the number of joints, as it enables a wire to be drawn through from the switchboard to the lamp in one uncut length.

One of the methods by which a lamp is suspended from a line of wiring is illustrated in Fig. 4. Wires for several lamps are passing through the length of horizontal tubing which, at this place, is supported from the ceiling by means of a light

Digitized by Google

cast-iron hanger. A T joint is made by flanging the fuse-box on to the lower part of the tube, and from the porcelain fuse-holder, which is contained in the lower part of the T, and which is protected by an ornamental brass casing, the covered flexible wires are dropped down to the lamp. One of the isolated wires is bent down to the positive fuse, and the central twisted return wire is connected to the negative fuse by a readily-jointed short length of bare wire. The negative fuse is shown by a dotted line, and the positive fuse is symmetrical with it on the other half of the porcelain holder.

It has been possible to give in this short article a description of only the main features of this mode of wiring, which has been most thoroughly worked out. The system has been subjected to a trial of several years' work in the lighting of many buildings, and has been found to fulfil the requirements of an effective mode of wiring. As was remarked in our former notice of this system, it is particularly well adapted for banks, offices, shops, churches, and other public buildings where the outer tubes can be boldly run without need for concealment. We understand that as it is merely fixed to woodwork by screws, the wiring and its cover remain a "tenants' fixture." In one or two cases closely spaced insulators have been drawn into compo tubing. This suggests a very convenient form of conductor for ordinary house-wiring, and we are informed that for the larger sizes, taking ten amperes or so, such a cable with one or more pairs of wires can be supplied at the price of first-rate rubber insulated cable and casing. The insulators would, of course, have to be set close to allow an easy bend to be made at any point.

CURIOUS EFFECT OF LIGHTNING NEAR QUEENSTOWN.

We have received from Mr. C. G. Doran, of Queenstown, some interesting particulars of the effects of a thunderstorm which passed over that town on June 19th last. The storm approached Queenstown from a south-easterly direction, and seems to have been of a singularly destructive and deadly nature; for several

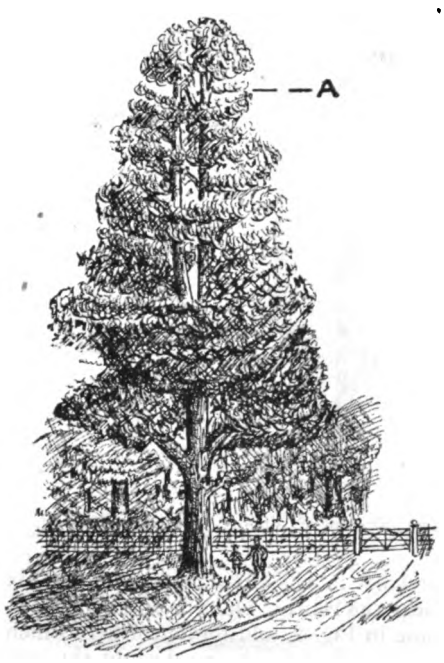

Fig. 1.

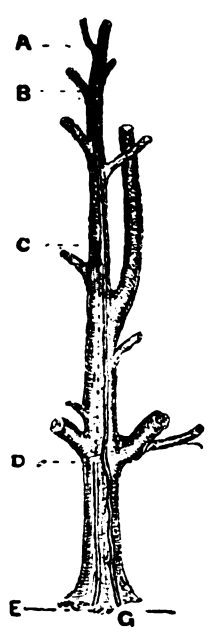

Fig. 2.

deaths resulted from the lightning. When immediately over the island of Fota, a beautifully wooded island in Cork Harbour, on which is situated the residence of Mr. Smith-Barry, M.P., a vivid flash struck the top of a lofty elm, which stood somewhat apart from the plantation of other trees, and about 9ft. from an iron fence which surrounded the thicket in which these trees grew. Fig. 1 shows the tree when viewed from the N.N.E. It will be noticed that towards the middle of its height the trunk divides into two stout limbs, which are but slightly separated and run parallel to one another to the top. The estimated height of the tree is 60ft., and its girth at a point 2ft. above the ground is about 8ft. The lightning flash struck the northern limb at the point indicated by the letter A, which is nearly 50ft. from the ground and several feet below the top of the tree. The branches and foliage above this point do not appear to have been affected in any way by the lightning. Passing downwards, the discharge grooved out a narrow channel in the bark and outer timber, till it reached the point B, in Fig. 2, when it suddenly shifted round the trunk to a point S by W; it then followed the tracks indicated by the letters, C, D, E, and G, to the ground. In Fig. 2, the foliage is omitted in order to show the trunk more clearly, and it may be well to remark that the diagram is not intended to convey that Fig. 1 became reduced to Fig. 2 by the lightning. At the point C, which is about 25ft. from the ground, the discharge seems to have divided, a portion taking the course to G and another portion travelling beneath the surface, through the wood tissue till it reached D, where it again appeared on the surface and chiselled out a downward course to E. Wherever the discharge travelled over the surface of the timber it seems to have slotted a clean channel in the bark of uniform width and thickness, and to have splintered out the underlying wood tissue over an equal width. We have received samples of the bark and wood, and it appears that the width of the strip of the former material which was peeled off along the groove, A to G, was uniformly an inch and a-half. The second groove, D to E, was, however, only an inch wide by about an inch deep, *i.e.*, the depth of the bark alone. The groove in the wood, wherever it occurred, was uniformly an inch and a-half wide by a quarter of an inch deep. The portion of the discharge which took the course C, E, passed to earth along one of the roots of the tree, which it violently disturbed. The other portion disappeared at G without doing any further apparent damage.

POSSIBLE AND IMPOSSIBLE ECONOMIES IN THE UTILISATION OF ENERGY.*

BY PROF. ALEX. B. W. KENNEDY.

(*Concluded from page 393.*)

I have reserved to the end some discussion of possibilities and impossibilities in connection with some complete industrial processes. Let us take first the generation and distribution of electricity, a matter which is of such keen interest now to so many of us, whether from the point of view of economy in production or economy in our quarter's bills!

The various stages of Fig. 9 tell a tale which, perhaps may interest you. They represent the gradual degenerative process by which the chemical energy of combustion is converted into electric light. To the left hand of the diagram is represented the boiler process, and the various transformations are represented from left to right, until the lamps are arrived at on the right hand of the figure. Similar letters are used in each section of the figure for similar quantities of energy. In each section the losses of the section before are written off, and the heat actually carried forward is called 100 per cent. K represents the losses in the boiler, which is assumed to have an efficiency of 80 per cent. H represents waste mainly due to condensation in steam pipes, and also to the driving of pumps, and other such losses inevitable in a central station. The third section represents the whole heat which has been received by that portion of the steam which actually found its way to the main engines, and of this, G is the part unavoidably lost from thermo-dynamic limitations (*see* Fig. 4). In Section IV. the heat actually received by the engine is called 100 per cent. Of this, the area F is wasted, and the remainder turned into work. Section V. shows the whole heat turned into work by

* Lecture given at the Royal Institution, April 21, 1893.

Digitized by Google

the engine as 100 per cent., of which the area E represents the energy necessary to drive the engine itself, which, therefore, never reaches the dynamo. In Section VI. the energy received by the dynamo is taken as 100 per cent., and the area D represents the dynamo losses, which are wonderfully small. The energy—now in the form of electrical energy—which leaves the terminals of the dynamo, is represented by 100 per cent. in Section VII. Of this, a certain proportion, sometimes small sometimes large, but here represented by C, is expended in mains, transformers, or batteries, and never reaches the lamps. Finally, at the right-hand side of the figure we get the energy received by the lamps as 100 per cent., out of which only this small, almost insignificant, quantity A is turned into light, the huge remainder B being once more converted into heat. If the side of the area A in Fig. 1 be looked at, it will be seen what an insignificant quantity of the whole heat of combustion it actually and finally turns it into its intended purpose. The result savours a little of the ludicrous. Let us go back and review its possibilities. The losses K, I need not deal further with. H represents losses, about which we engineers feel very sore, and which sometimes try our temper and our patience greatly. It is so annoying to have a kind of additional gratuitously-superfluous loss—not dealt with in text books, not recognised as having any kind of respectable existence—thrust in upon us. The temptation to muddle it up with K or G is very great; but if it is really to be got rid of, or even greatly

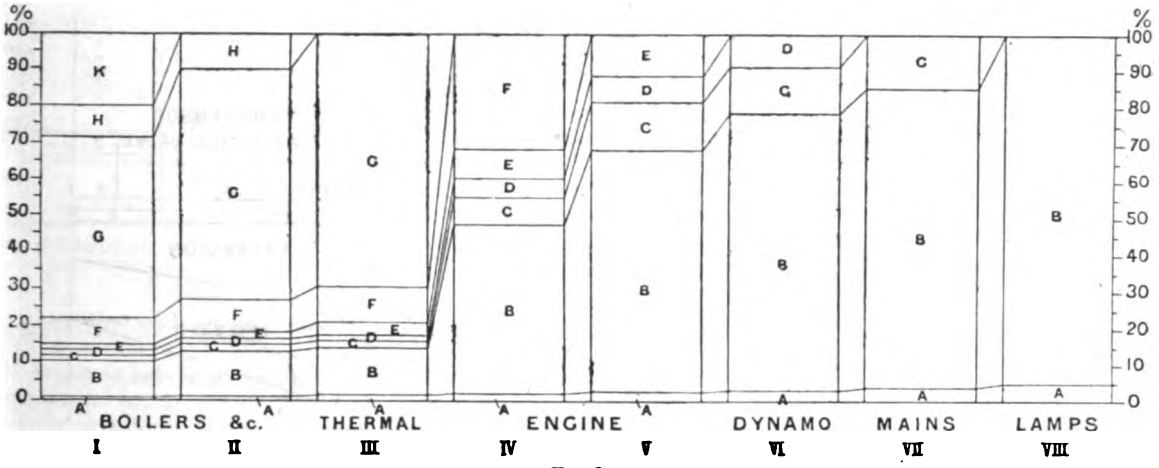

FIG. 9.

reduced, it must be faced. I will not, however, trouble you about this; it is a difficulty in domestic politics, and should, perhaps, not be brought into publicity. To quote one of Mr. W. M. Conway's remarks in an entirely different direction, "It would be a breach of confidence to let the ordinary reader into the secrets of these things."

G and F I have already dealt with in connection with Figs. 4 and 5. E and D do not look very promising as fields for radical improvement. There are few things I think more creditable to modern engineers than the smallest of the losses represented by D. Only about 60 years ago Faraday made his copper disc machine, which, I believe, is still in this building. It is hardly 25 years since dynamos, as we now understand the word, were invented. Even 12 or 15 years ago the description of a dynamo as a combination of brown paper and copper wire stuck together with shellac and dotted over with mica was not without some sort of foundation in fact. But now, thanks to the combined scientific knowledge and mechanical skill of the engineers who have taken this matter up, some of the foremost of whom I have now the pleasure of seeing in this room, the dynamo is not only excellent in its mechanical design, but so high in its efficiency that it can, and does, give out as electrical work something like 92 per cent. of the mechanical energy which it receives from the steam engine. Of the remaining 8 per cent. about a quarter is taken up in supplying the magnetising energy, and I daresay the dynamo makers would tell us that they would make the remainder almost disappear if they could only get people who would pay a high enough price for the machines.

I do not think that the distribution losses C are likely to be reduced to any very sensational extent below the figure at which I have put them. We frequently hear of their almost negligible magnitude, but whenever they get really measured, the sum of a number of things which separately are supposed to be so minute appears to be anything but negligible. No doubt the 15 per cent. loss will be gradually driven back to 10 per cent.; but it will be hard work, and will come about only by degrees and by care and pains in detail, not by any new system of distribution or by any striking invention.

But truly in our last stage we have got one in which improvement is needed and in which we all hope that enormous improvement is possible. Moreover, here I can no longer adopt the Philistine attitude, which I fear I have had to take up so much, and say that improvement is a matter of detail and of common sense only. On the contrary, here is a case where we know beforehand that we may any day be surprised by a discovery, on the part of one of the many men who are devoting time and thought to the matter, which may even enable us to multiply manifold the amount of light which we can obtain from a given quantity of energy. At present to obtain light, I speak of glow lamps only, we have to pass a current through a carbon filament in such a fashion as to make it white hot, and it is only because it is white hot—*i.e.*, because we expend energy in heating it up—that it gives light. Of the whole electrical energy received by each of the lamps in this room, probably 95 per cent. is expended in heat and only 5 per cent. in the actual light rays, as is indicated in my diagram by B and A respectively.

To obtain light without heat, or with a minimum of heat, that is the point. Much as I should like to tell you from what direction the improvement must come, I fear I cannot. Mr. Tesla gave a certain lecture here which many of you may remember; you will certainly do so if you heard it. Our friends in the newspapers told us next day, possibly misled by some pardonably incautious enthusiasm on the part of the lecturer, that at last the hour had come, electric light was to roam the universe at large, and you had only to put a tin plate on the ceiling and hold a lamp in your hand for the whole room to be lit up! No more quarterly bills at 8d. per unit, or even 6d., no wiring of houses—universal brotherhood and current for nothing. Perhaps the papers would not have been so sanguine if they had known, what I believe was the fact, that the gas engine which lights this whole building easily was hard put to to supply energy for Tesla's experiments, and you will remember that the most striking and beautiful of them hardly did more than make the lecturer visible. It would be sanguine to hope that the light of the future will be economically worked out on those lines.

It is often suggested that we should go to the glow-worm and study that little animal. Any of you who have tried will no doubt remember what a very disappointing little animal he is. His light is so clear from a few yards off that you think

Digitized by Google

he must be really bright, but when you examine him from the point of view of looking for *light* you find there is a terribly small amount to look for, a candle would be a conflagration in comparison. It is possible that the glow-worm line—if we only knew exactly what the line was—is the one to be pursued, but it also looks unpromising at the outset. But no doubt the man who works out the problem successfully will be of sterner stuff and more sanguine temperament than to criticise destructively at the outset. People who criticise never make inventors.

Fig. 10 represents, in a condensed form, the losses which occur in the transmission of power on an electric railway or tramway. Here, I have not gone back to the boiler, but have taken the work done by the main engine as 100 per cent., so that Fig. 10 really corresponds to Sec. V. of Fig. 9.

Fig. 11 is drawn in the same way, and represents the result of some experiments which I made in the year 1889 in Paris, in connection with Popps's system of compressed-air distribution. Time fails me to discuss these diagrams in any detail; I merely put them before you as possibly of interest.

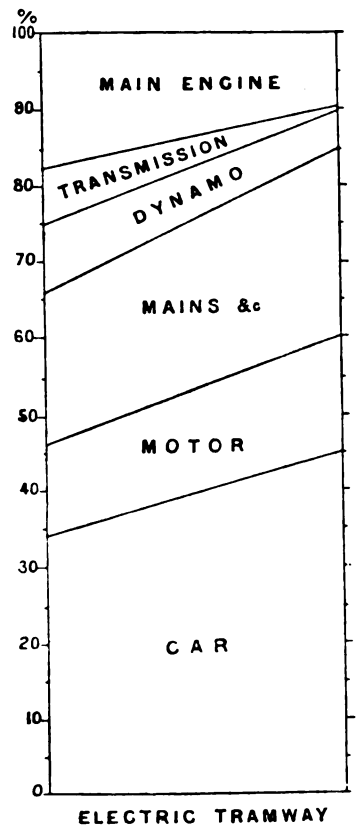

Fig. 10

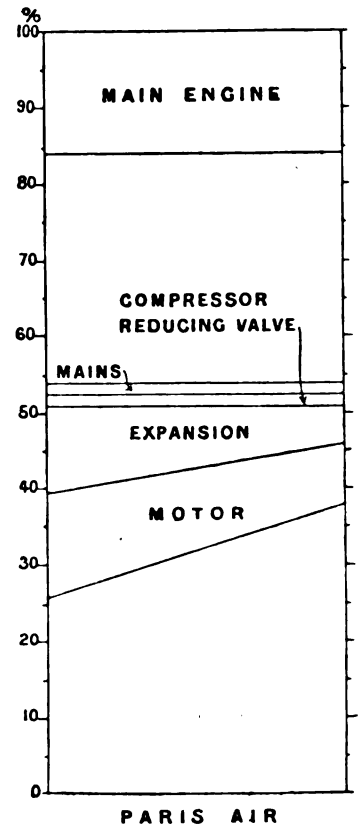

Fig. 11.

I am sorry, so close to the end of my lecture, to have to spring a new idea altogether upon you; but it is a matter which has so close a relation to my subject, and one which is so much overlooked, that I must not leave it out. I have given you certain ratios, certain efficiencies, which can be, have been, and are constantly being reached in the carrying out of physical processes on a large scale. But in estimating and comparing the economy possible in different cases, we must be careful that the conditions are similar. Thus in a boiler test an efficiency of 75 per cent., or even 80 per cent., can be obtained with care. But this supposes the boiler to be steadily and continuously worked. In point of fact, except on board ship, and in a few cases on land, our working conditions are widely different. In an electric light station, for instance, one boiler may be required all the 24 hours, one more for 20 hours, one more for 16, and two more for 8 hours. It is clear that for all of them except one these are long hours when they are doing nothing, but during which, nevertheless, they are burning some coal, if only a little. I find that with very great care the loss due to this cause can be brought down to from 8 to 10 per cent. I have often heard it estimated at double this figure. It is quite possible that one may find some way presently of reducing this loss still further, but at present even in the best practice it makes the average results of continuous work to fall woefully short of the results of tests even of considerable duration.

With engines and dynamos, but particularly the former, we get another set of conditions which tend to reduce the average economy below that due to experiment. The wasted work shown in Fig. 9, Section V, and marked E, is not proportional to the full power, but is practically constant at all powers. Hence at half power, instead of 12 per cent., we waste 24 per cent., at one-third power 36 per cent., and so on. It is easy to say that engines should always be worked at full power, but as the power required is very frequently quite beyond the control of the engineer it happens that the average load in almost all cases, except that of marine or pumping engines, is much less than the full load, hence a corresponding reduction of actual efficiency. As in the case of the boilers, the possibilities here are only of improvement by skilful design and management. They are none the less to be looked for and to be constantly kept in mind. Much more can be done by most of us by economy in this direction than is to be hoped for by any radical improvement in maximum possible efficiency. The work of the executive engineer is to take the *maximum possible* as he finds it, and devote all his energies to bringing the *actual average* as near that *maximum* possible as he can. These problems may be summed up as those affected by what Mr. Crompton has most happily called *load factor*.

There is yet another direction in which possible economy is to be looked for, a very fascinating one, and by no means an unpromising one. Look for a moment again at Fig. 9. Except only the process at the lamp itself, all the transformations have fair economy, so good that one sees at once that no radical defect exists in them. But cannot some of these be done away with altogether? It is the number of them that tell, and bring down the final result. Even half-a-dozen transformations of 90 per cent. efficiency each bring us down to about 50 per cent., or cannot we substitute for III. in Fig. 9, some more effectual process?

If an ordinary gas engine be substituted for a steam engine we cut out the question of boiler efficiency, or rather we leave

Digitized by Google

the corresponding losses to the gasworks. Whether it is more economical that they should take place then or in our own boilers depends on the price and quality of gas. At the same time we substitute the higher efficiency of the gas engine for the lower of the steam engine, which may be a very important matter. It is practically equivalent to cutting G out altogether. Still more fascinating are the ideas of obtaining electrical energy direct from steam jets and so doing away with the engine at least, or of consuming our carbon in enormous primary batteries instead of burning it in furnaces, and so at one stroke clearing off boilers, engines, and dynamos. One wishes in vain that one could see ground for any kind of reasonable hope that such methods would be practicable!

Of another kind is the possibility at present much talked of, namely, the substitution not only of a gas engine for a steam engine, but at the same time also of a gas producer for a boiler, so that the motor fluid should be producer gas made on the premises and not steam or coal gas from public mains. There seems no doubt that the combination, although it does not much reduce the number of transformers, gives under certain conditions a very high economy of fuel indeed. I do not think the evidence before us is as yet sufficient, although I hope it shortly will be, to enable us to say how far under ordinary working conditions the actual combined efficiency of the whole plant will be distinctly greater than that of existing systems. The theoretical maximum efficiency, certainly, is much higher. The whole cycle of processes and transformations is shown in Fig. 12, which is drawn so as to compare directly with Fig. 9, and about which, therefore, I need not peak in detail.

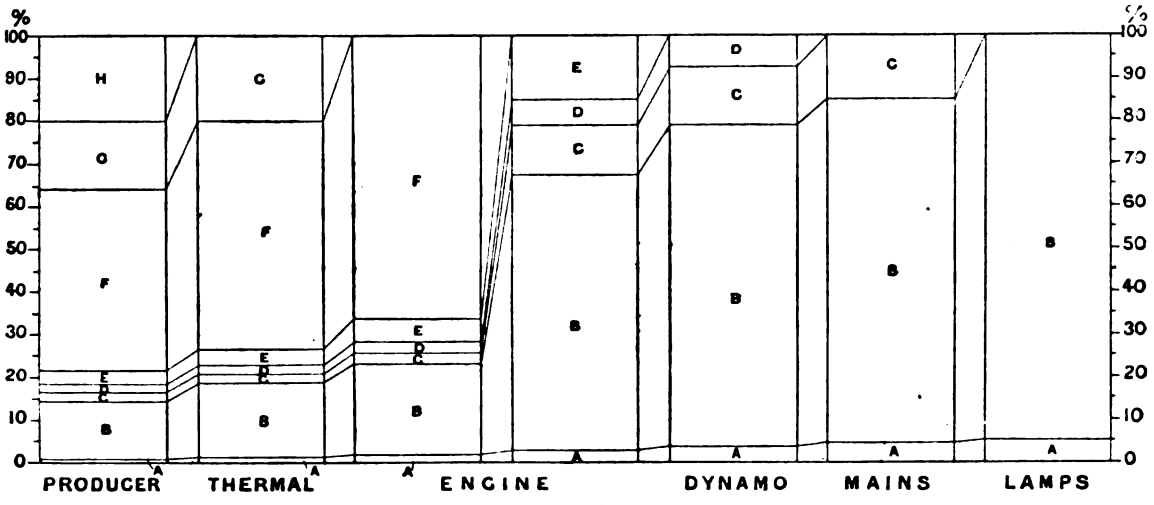

Fig. 12.

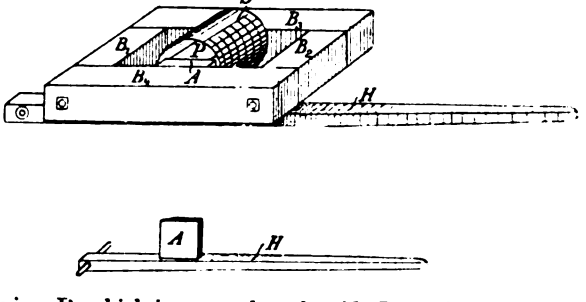
Still one more matter, and I have done. We have heard a good deal lately, from many different quarters, of the enormous possibilities of economy which lie to our hands in the way of utilising as fuel the dustbin and other parish refuse which is now being so largely burnt to waste. Of course this stuff has the vast advantage that it costs nothing, even for cartage, and that at present all the heat due to its combustion is being thrown away. But I cannot help fearing that like most things that cost nothing it will be found to be worth very little more than it costs. I schemed sometime ago the boilers at a station in the North to try the experiment of using waste gases from a town destructor, but have not been sanguine enough to hope that I can do more in this way than save some of the cost of banking fires, or running at very low load. I shall be delighted if I am mistaken in my estimate. In any case it has to be remembered that the dust destructor works on uniformly day and night, delivering a uniform amount of heat, while the boilers of a lighting station want heat non-continuously in most variable fashion. If, therefore, more than a very small fraction of the destructor heat is to be utilised, arrangements must be made for storing that heat somehow, so that it can be drawn upon as it is wanted. With thermal storage there is at least a theoretical possibility of using most of the destructor's heat, without storage 10 per cent. of it is probably the largest amount that can possibly be utilised.

To sum up the whole matter in the way of possibilities and impossibilities, there does not seem to be anything very startling before us in the way of possible economies, except in the two directions of efficiency of lamps as light producers, and of bringing up gas engines to their theoretical maximum. In other respects matters are running along lines which I have endeavoured to indicate, and along which they will doubtless develop more or less rapidly, but always less and less rapidly as they get nearer their limiting efficiency. There is no one point in which we have not some measurements which enable us to set bounds to the possibility of improvement along any known lines, and thus we have means for gauging the value of the pretensions made by each new method, or scheme, or invention, as it appears—not merely guessing at it, but actually estimating its possible value numerically. For those of us who are not born to be inventive geniuses there is always the consoling thought that the difference between good engineering and bad engineering in economy, with the very same materials, is very much greater than the difference between good engineering and any probable improvements upon it. And meantime, we find our hands sufficiently full in trying to keep up to the best existing standards, pending the time when Messieurs the discoverers show us how to get on a little further.

A SIMPLE APPARATUS FOR COMPARISON OF THE MAGNETIC QUALITIES OF SAMPLES OF IRON.*

BY DR. BEHN-ESCHENBURG.

The object of this instrument is to compare the qualities of different kinds of iron as regards induction produced by given forces, and the value of the residual induction. It consists of a rectangular framework made of four blocks of wrought iron screwed tightly together (B_1 B_2), and a coil S, which is slipped on to the



test piece P, which is screwed to the side B_3 of the frame. A small wrought-iron plate A, mounted on a lever H, is so arranged that it fits into the gap between B_4 and P_1, and carries the test coil, which is connected in the usual manner, to a ballistic galvanometer. The values of total and residual induction for a given number of ampere-turns are determined by breaking the current in the coil, and then suddenly removing the plate A.

ELECTRICAL CONGRESSES AND ELECTRICAL UNITS.

It is generally better, says BACON, to deal by speech than by letter, and the modern mania for congresses may perhaps be taken as an indication that this is so. Congresses, however, like exhibitions have of late fallen into no little disrepute amongst those members of the community who refuse to be "ravished with the whistling of a name." The reason for this is not far to seek. As our dictionaries tell us, congresses are properly assemblies of the delegated representatives of sovereign states for the purpose of considering matters of international importance. Were they always so no healthy minded eupeptic individual would question their utility or quarrel with their pretensions. But now-a-days whenever two or three men of learning or leisure are gathered together they must needs straightway hoist the congressional flag, and do their best to give an odour of international sanctity to their proceedings. There is perhaps no particular harm either in legislation or science by picnic; indeed, "for those that like it, that's the very thing they like." On the other hand, considerable harm is done by giving to any miscellaneous scientific gathering the title of congress, a title which should by rights be reserved for assemblies of official delegates called together, not for the discussion of minute details and the reading of peddling Papers, but to consider matters of international importance and for the solemn ratification of a compact previously arrived at by negotiation or discussion. A congress is not the place for polemical debates or the promulgation of new ideas. As in political so in scientific congresses, the function of a delegate should be narrowed down to securing a general agreement on certain previously discussed points. "Things," says BACON, "will have their first or second agitation; if they be not tossed upon

Digitized by Google

the arguments of counsel, they will be tossed upon the waves of fortune and be full of inconstancy, doing and undoing, like the reeling of a drunken man." With a view, no doubt, of preventing the occurrence of anything of this unseemly character at the fifth International Electrical Congress, which commences its labours at Chicago on Monday next, a sub-committee of the American Institute of Electrical Engineers drew up some seven months ago a lengthy and elaborate programme which they recommended should receive its "first agitation" at the hands of the technical journals and at the meetings of the various scientific societies concerned. This certainly was a step in the right direction, and the request for a preliminary discussion was fairly well responded to. The programme, however, was far too ambitious, and contained far too many novelties to be in a fit state for the irrevocable ratification of an International Congress, even after half-a-dozen "agitations." We have been punished for our sins of precipitancy in the past by being dogged for all time by an irrepressible 4π—to remove which certain eminencies would have us recast our entire system of electrical units—and we sincerely trust, therefore, that this programme will not get further than the lower Chamber of the Congress, and that the Congress proper, to wit, the official delegation, will content itself with giving international sanction to the decisions of the Board of Trade Electrical Standards Committee—decisions which embody practically all that the electrical world is really ripe for in the matter of legal units and nomenclature, and which are the net outcome of sixty years of investigation and accurate measurement by the leading men of science of all nations.

This coherent system of electrical units and nomenclature, which, after receiving the *imprimatur* of the Chicago Congress, will become legalised in the leading countries of the civilised world, has not been built up in a day. The foundations were laid by Gauss and Weber in the second quarter of the present century, and the good work was carried on in this country by Thomson, in Germany by Kohlrausch. It was in 1833 that Gauss first published his theory of an absolute system of magnetic measurement, and in 1851 that Weber promulgated the first definite system of current measurement in terms of absolute units. In the same year Lord Kelvin (then Prof. William Thomson) commenced to use the electromagnetic system of units in the reckoning of electromotive force and resistance, and ten years after, in 1861, he obtained the appointment of the historic British Association Committee on Electrical Standards. In 1870 this Committee published its final report at the Liverpool meeting of the Association, and it is this report that may be said to have assured the general adoption of a coherent system of electrical units having for basis the centimetre, gramme, and second. The members of this Committee at the date of the report were:—Prof. Williamson, Sir Charles Wheatstone, Sir William Thomson, Prof. W. A. Miller, Dr. A. Matthiessen, Prof. Fleeming Jenkin, Sir Charles Bright, Prof. Clerk Maxwell, Mr. Chas. Hockin, Mr. C. W. Siemens, Dr. Joule, Mr. Balfour Stewart, Mr. C. F. Varley, Prof. G. C. Foster, Mr. Latimer Clark, and Mr. D. Forbes.

An international system of electrical units is indeed a boon, inadequately appreciated though it may be by a generation that has never known anything else; but an international system of nomenclature is a desideratum of scarcely less importance. Whether the Americans decide to label their arc lamps with the current they require, the energy they consume, or the light they are supposed to give, is a matter of secondary concern so long as the current, energy, or supposititious candle-power is measured in the units adopted by the rest of the world. It would indeed cause a very Babel of units if the American unit of current were ten times as big as its European congener, the American unit of power one hundred times as large, and the American candle a mere farthing dip. But we do not think matters would be appreciably improved if the Americans, whilst employing the same units, were to adopt a narrow patriotic system of nomenclature. In truth, the last state would be worse than the first, with our ampere converted, say, into their "morse," and their "henry" jostling in fierce competition with the Central Institution "secohm" or the Paris 1889 Congress "quadrant." The happy idea of perpetuating the memory of the founders of electrical science by affixing their names to the different electrical units was due, as is generally known, to Mr. Latimer Clark and the late Sir Charles Bright, who first put it forward in a Paper communicated to the British Association in 1861. Both the general idea and the particular names proposed met with world-wide acceptance, and hence we have to day similarity of names as well as uniformity of units.

In 1881 began the era of International Electrical Congresses. The Paris Congress, held in September of that year, sanctioned the adoption of the C.G.S. system and the derived practical units; the names, ampere, ohm, volt, coulomb, and farad being settled upon. It was also decided that the standard of resistance should be a column of mercury of one square millimetre cross-section, the length of the column to be determined by an international committee to be appointed. Amongst the English delegates at this the first International Electrical Congress were Earl Crawford, Sir Charles Bright, Prof. Hughes, Sir William Thomson, Mr. Warren de la Rue, Sir William Siemens, Mr. Graves, Mr. Preece, and Prof. W. Grylls Adams. In May, 1884, Paris was again the scene of an International Electrical Congress, the main outcome of its labours being the adoption of the so-called legal or 106-centimetre ohm and the Violle standard of light, neither of which met with much enthusiasm. Electrical energy was apparently overflowing in 1884, for in the autumn of the same year there was another gathering of electricians at Philadelphia. This assemblage was called a Congress, although there were no official delegates, and the pernicious and uncongressional practice of reading miscellaneous Papers and discussing them was not only permitted but encouraged. At this meeting the "watt" was born, the Violle standard of light was denounced as impracticable, and the engineering world ordered to raise the value of the horse-power by 33·3 per cent. in order to make it equivalent to 1,000 little watts, and thus save the time and temper of calculating electricians. It is satisfactory to find that this journal raised a gentle protest against that ukase, and meekly hinted that it made the Congress look a trifle ridiculous. The next so-called Congress was held in Paris during the Exhibition of 1889. Official delegates there were none, but officious delegates there were many, who endeavoured to secure amongst other absurdities a congressional decree to the effect that the unit interurban telephonic conversation should be one of three-minutes' duration. At this meeting the "secohm" received its *quietus* and the "quadrant" reigned in its stead; the watt was again adopted as the unit of power with the kilowatt as its commercial derivative; the joule was sanctioned as the unit of work, and the "bougie-decimal" was accepted as the practical unit of light. The passing of the Electric Light Amendment Act of 1888 having resulted in a great extension of the system of statutory electricity supply from central stations, *legal* standards of measurement were soon felt to be necessary, and on December 16, 1890, the Board of Trade appointed a Committee to consider the question. The first report of this Committee

Digitized by Google

was dated July 23, 1891, the second was dated November 29, 1892. The purport of these reports is too well known to need recapitulation; suffice it to say that they recommended the *legalisation* of the electromagnetic system and the adoption of a standard ampere, ohm, and volt; the resistance of one ohm to be represented by that of a column of mercury at 0°C 106·3 centimetres long, of constant cross-section, and weighing 14·4521 grammes. As soon as the resolutions of this Committee have received the international sanction of the Chicago Congress, the electromagnetic system with its practical derivatives and their quaint nomenclature, will become crystallised for all time by the legislative acts of the nations of the civilised world.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 397.)

It will thus be understood that the ratio of the cold resistance to the hot resistance of a flashed filament depends entirely on the ratio of the amounts of the two kinds of carbon of which it is composed, a much-flashed filament having a larger ratio than one only slightly flashed. The resistance of a filament measured cold gives no indication of its hot resistance unless that ratio is known. The most usual ratio is about two to one, though it is often above or below that amount. The specific resistance of arc-lamp carbons (cold) will vary from 13,000 microhms per c. c. to less than that of amyloid, according to the method of manufacture, moulded carbons having a higher specific resistance than squirted ones.

Different kinds of carbon have different emissivities; that is, they radiate heat and light at different rates, so that, at a given temperature, carbons of the same size but of different makes require different amounts of power expended in them in order to maintain that temperature. This curious property appears to be connected with the nature of the surface only, and has nothing to do with the material underneath the surface.

It is well known that a hot polished copper rod, if covered with lamp black will cool much more rapidly than a similar rod not blackened. In the same way a hot lamp filament with one kind of surface will cool faster than a similar filament with another kind of surface. A filament made of amyloid carbon will cool faster than the same filament if it be flashed in pentane in the way described. Suppose that an amyloid carbon filament be made into a lamp and tested, and that it is found that at 4 watts per candle power it takes 84 watts and gives, consequently, a light of 21 candles. Let the same filament be taken out of the lamp and flashed a very little by the pentane process and then be made into a lamp again and tested. Let it be run at the same temperature as before, and it will be found to give only 15 candles and take only 60 watts. Now that it is flashed and has a different kind of surface it loses heat much more slowly, and a less expenditure of power suffices to maintain it at the former temperature. It must be particularly noticed, however, that there is a corresponding decrease in candle power. Let it be run at its original candle power (*i.e.*, 21) and it will be found to take about 68 watts, equal, that is, to about 3¼ watts per candle, considerably less power than before flashing. Many people have supposed that results like this indicate that the flashed filament is a more efficient one than the unflashed. This, however, is not the case at all. The filament now giving 21 candles is at a higher temperature than it was when giving that candle power before being flashed. If it had not been flashed at all, it could have been equally well run at this temperature and efficiency, only it would then have given about 28 candles and have taken about 90 watts. The filament has simply become less emissive. It radiates more slowly.

The extent of surface of filaments will vary with different kinds of surfaces from 6,000 to 10,000 square mils per candle power at the temperature of 4 watts per c. p. (equal to 100 to 170 c. p. per square inch). When run up to the temperature at which the best carbon begins rapidly to disintegrate (0·8 w. per c. p.) as much as 1,900 c. p. per square inch may be reached. The crater of an arc-lamp carbon is said to give about 45,000 c. p. per square inch.

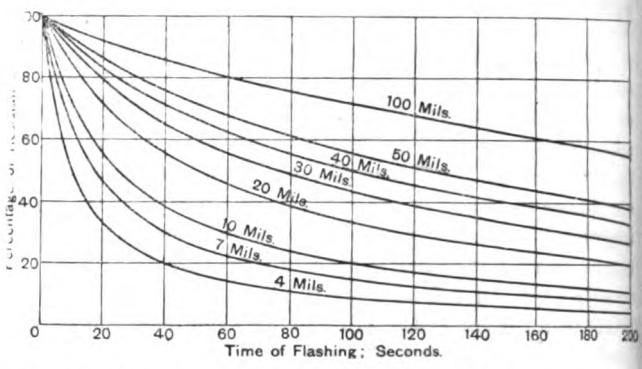

FIG. 16.—Curves showing Effect of Flashing on the Resistances of Filaments of Various Diameters.

The change in emissivity produced by flashing gives an additional reason for carefully reproducing the conditions under which that process is carried out for each filament so that they may all come out alike.

The actual amount of the error in the voltage of the lamps produced by the several causes mentioned will now be considered.

An error in the thickness of a filament is a serious one. Suppose that a filament for 100-volt 15-c. p. lamp at 4 w. per c. p. (= 60 w. total) should be 6 mils in diameter, but that the conditions of flashing have not been quite right, so that the diameter comes out at 6·4 mils, an increase of 6·6 per cent. in diameter, and therefore in surface. The filament will now

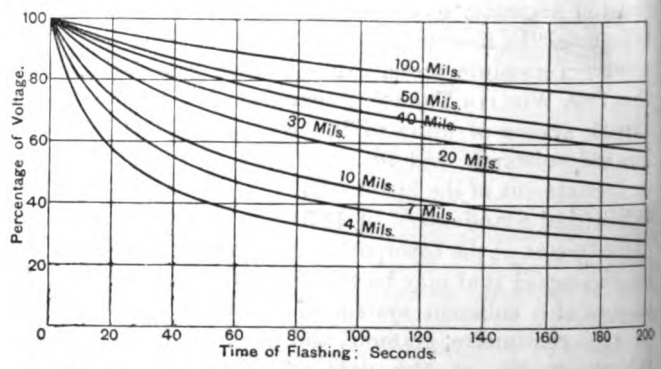

FIG. 17.—Curves showing Effect of Reduction in Resistance, due to Flashing, on the Voltage of Filaments of Various Diameters.

require 6·6 per cent. more energy, and will be increased a like amount in c. p. It will take 64 watts and give 16-c. p. But it was flashed to the resistance for a 15-c p. lamp (166 ohms.) not for a 16-c. p. one. Consequently, it will take 103·2 volts and 0·62 ampere, to give the right temperature. Or if run at 100 volts it will give only about 13·5 candles, and an efficiency of 4½ watts per c. p.

It will be noticed that, though the increase in diameter is 6·6 per cent., the increase in voltage is only about half that amount, the error being divided between the E.M.F. and the current. The percentage error in voltage will be about one-half that of the diameter for ordinary variations.

With regard to errors in emissivity due to the conditions of flashing being wrong, the effect is exactly the same as for

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of re-publication reserved.

Digitized by Google

errors in thickness, an increased emissivity having the same effect as an increase in diameter. A similar result will be produced if filaments are mounted with wrong lengths. This is usually looked upon as a less serious matter than differences in thickness, as it is supposed to be easy to mount filaments to the proper length. Suppose a filament is to be five inches long. One per cent. is 0·05 inch. That is to say, it must be mounted with an error of not more than 0·025in. on each leg, in order to be within 1 per cent. It is, therefore, very important to be exact in the matter of length.

With errors of resistance the same kind of result occurs as with errors in surface. One per cent. error in resistance will produce only about one-half per cent. error in voltage. This

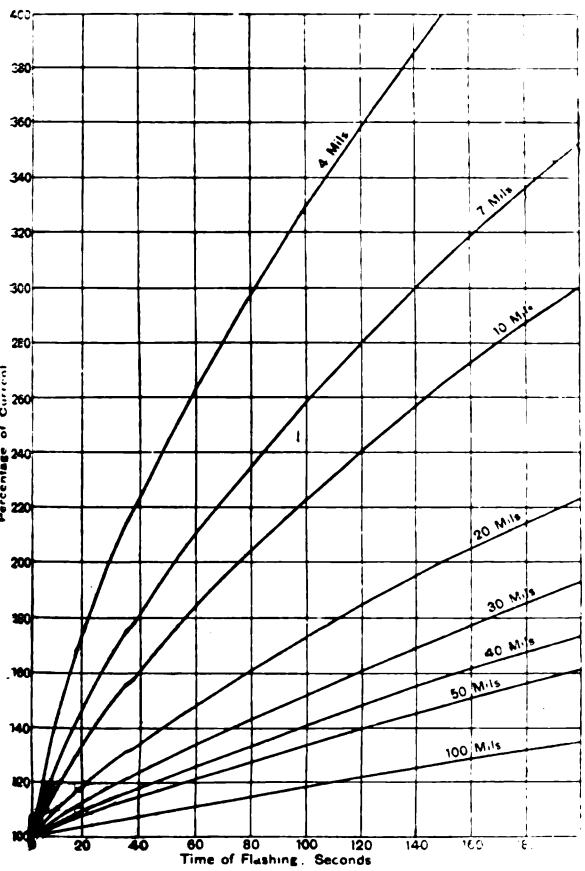

Fig. 18.—Curves showing Effect of Reduction in Resistance, due to Flashing, on the Current for Filaments of Various Diameters.

must not be understood to apply to very large differences in resistance. For instance, a 50 per cent. reduction in resistance gives more than 25 per cent. reduction in volts. The actual effect on the volts and current of a gradually diminishing resistance is shown in the accompanying curves, Figs. 16, 17, 18. The resistance is supposed to be diminished by flashing, the thickness of the deposit of flashed carbon being considered as proportional to the time of flashing, the rate of flashing being such that a 4-mil filament is reduced 50 per cent. in resistance in ten seconds.

It must be understood that the effect of reduction in resistance alone is shown in these curves. The actual results of flashing, taking into consideration the change in resistance, emissivity and thickness are fully dealt with in a subsequent chapter.

It has been shown that the time of flashing is an important consideration, and that it is better to flash always to about the same length of time and use filaments of different diameters, which will permit of this being done, than to use only a few sizes of filaments and vary the time of flashing.

It is therefore necessary to consider the relation of the sizes of filaments to the candle-power, voltage and temperature at which they are to be run.

(To be continued.)

LORD KELVIN'S NEW ELECTRICITY METERS.*

BY ANDREW W. MEIKLE, M.A.

In 1887, Lord Kelvin reported to the Society regarding the progress of his work upon electrical measurement, in a Paper entitled "A Double Chain of Electrical Measuring Instruments." Since that time much has been done to improve and complete the *chains* then spoken of, and they now form the recognised standards in all parts of the world. The chain of balances has been extended, and now affords a means of accurate measurement from $\frac{1}{100}$th to 10,000 amperes. The chain of electrostatic voltmeters has been made to suit all ranges from $\frac{1}{100}$th of a volt to 150,000 volts. Besides these two types of standard instruments, others have been made to suit the requirements of power and light installations. These are made mostly on the plan of the ampere gauge (Fig. 1), which has actually been constructed to suit all ranges between $\frac{1}{4}$th of an ampere and 15,000 amperes. Some special instruments have been designed, from time to time, to suit various requirements, and I am pleased to be able to show the Society an instrument designed for the Edison Electric Illuminating Company of New York, and which is, without doubt, the largest voltmeter in the world. I will describe it later on.

I now wish to describe another chain of instruments which are intended to record the amount of electrical energy consumed in a power or light installation. The instrument consists of an electrically-driven clock, and of an electric indicator which shows the

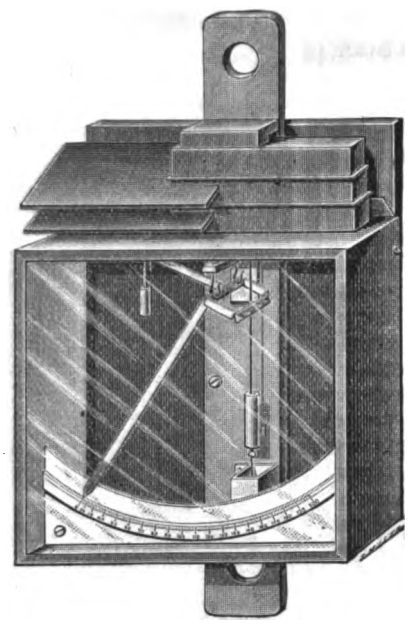

Fig. 1.—Ampere Gauge.

strength of the current passing at any particular moment. This instrument is shown in Fig. 2, and details are given in Figs. 4, 5, and 6.

Before entering into these details of this instrument, as a recording meter, I shall first describe the electrical indicator, and afterwards give a description of the indicator and clock, as forming a recording electricity meter.

The electric portion of the meter consists of two parts—

1. A main coil, D (Figs. 5 and 6), which carries all the current supplying the lamps.

2. A movable electromagnet suspended upon two spiral springs (Figs. 4 and 5.)

The main coil has a number of turns of copper rod wound as shown in Figs. 5 and 6. The number of turns and thickness of the rod vary according to the current range of the meter; thus, a meter for 25 amperes has about 75 turns in its fixed coil, while a meter for 250 amperes has only eight or nine turns of heavier conductor. In the earlier forms of the meter the coils were made of a stranded conductor formed of a number of silk-covered wires, but the present form of coil has many advantages. It has its surface open to the air, and so quickly radiates off the heat generated by the passage of the current. It has also the advantage of giving a more intense field for a given cross section of conductor, because the whole conductor lies nearer the axis of the solenoid than it does in the stranded coils, the latter losing in concentration by the thickness of insulation on its different wires.

* A Paper read before the Philosophical Society of Glasgow.

Digitized by Google

The electro-magnet consists of a soft-iron bar, on which are rolled a great number of turns of very fine insulated copper wire. Soft iron is used in order to obtain sufficient force to overcome all frictional errors. The same phenomena could be obtained by the action of the main solenoid upon another solenoid of fine wire, but the force would be very feeble; this would also be the case if a permanent steel magnet were used. By the use of soft iron the force is increased more than 2,000 times over what it would be if a fine wire solenoid only were used. There is nothing new, of course, in the use of soft iron and a solenoid in electrical instruments. Many instruments have been made depending upon this principle, but most of them have not been very successful, because of errors due to residual magnetism in the soft iron. These errors are due to the fact that, if we magnetise a piece of soft iron and remove the source of magnetism, the iron will retain some of the imposed magnetism until it receives some shock or jar, when it returns at once to its original state. That is only the case with a piece of good soft iron; a piece of iron which is not thoroughly annealed will retain its magnetism in spite of a shock, and the amount of the residual magnetism is a very varying quantity, so that no good result can be obtained from it. This trouble in measuring instruments can be got over well enough for practical purposes by choosing the iron of suitable dimensions and using a very intense magnetising field. Lord Kelvin has done this in his engine-room ampere gauge (Fig. 1), in which he uses a solenoid of special construction, which gives a very intense field, and a soft iron plunger, which has a ratio of diameter to length of about 1 to 200. A bar of these dimensions is very easily saturated, so that it is found possible, with this instrument, to get a useful range free from residual errors of about 1 to 10. That means that an instrument suited to read to 100 amperes could not be used below 10 amperes, because it would show considerable uncertainty, and would not be sensitive. In this meter it is absolutely necessary that the scale throughout should be uniform—that is to say, that the electro-magnet should be pulled down a distance exactly proportional to the strength of current. It is found impossible to use the fine wire solenoid alone, because there is too little force to overcome the friction of the plunger on the side of the coil, and too delicate springs would require to be used. It is found impossible to use soft iron alone, because it does not give a uniform scale, and would be subject to the errors just mentioned. What is done, then, is to use a bar of soft iron, which is kept saturated by the current through the fine-wire coil wound upon it. The current through this coil is about $\frac{1}{40}$th of an ampere, and this is about 25 per cent. more than is sufficient to keep the iron fully saturated, and makes it for the purpose virtually a permanent magnet. This is, I think, quite a new departure in measuring instruments, and allows much greater masses of iron to be used with good results, and also enables a large range to be had from one instrument.

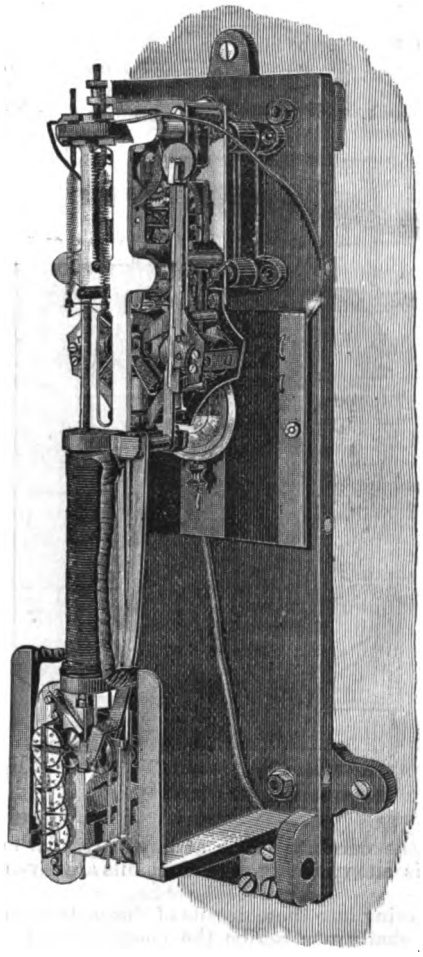

FIG. 2. Electricity Supply Meter.

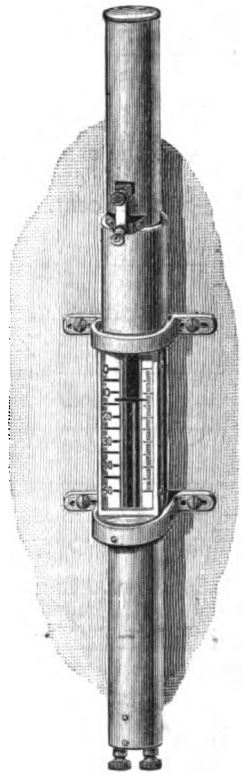

FIG. 3.—Tubular Ampere Gauge.

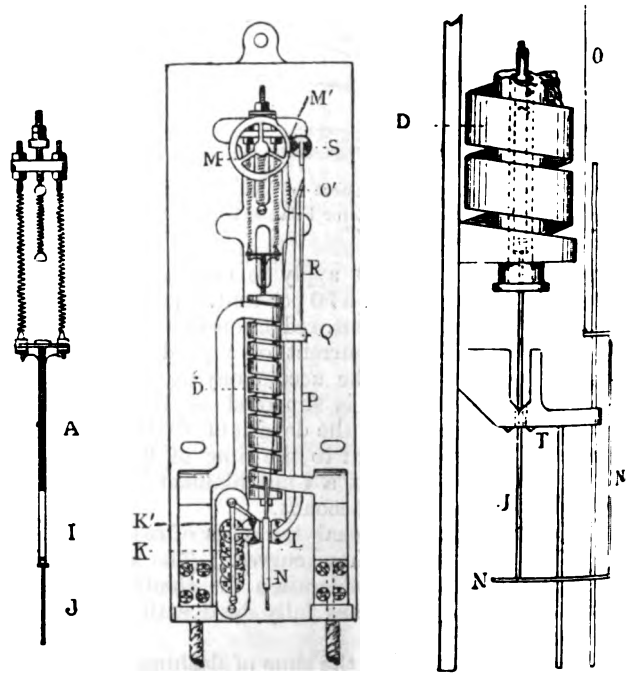

FIG. 4. FIG. 5. FIG. 6.

Details of Electricity Supply Meter.

In an instrument called the Tubular Ampere Gauge, made as now described (Fig. 3), a scale of equal divisions is procured from 0 to 50 amperes, or from 0 to 100 amperes, as will be seen. An instrument of this kind is very useful in a dwelling house, or other installation, where it is desirable to know if all the lamps have been put out, or what number of lamps are in action.

Digitized by Google

Having now described the principle of the electrical indicator, I ll speak of the details of the combination which forms the meter. ıe details are shown in Figs. 4, 5, and 6. The suspended electro- ıgnet is shown separately in Fig. 4.

At the bottom end of the electro-magnet, A, is attached a guiding be, I, and a loose bar, J, hangs on a projecting ring in the bottom the guiding tube. This loose bar hangs betwen two rollers, K′ d L (Fig. 5), which have broad, flat rims. The range of the

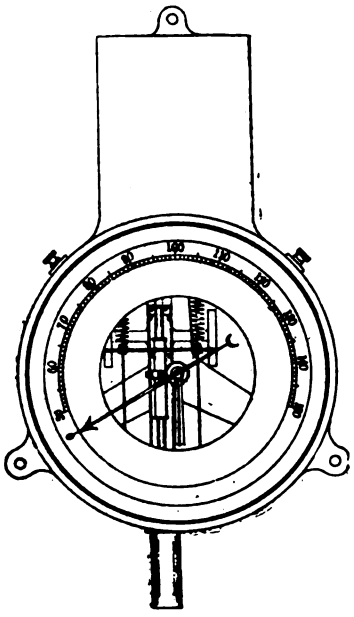

FIG. 7 Large Dial Voltmeter. External View.

ctro-magnet, A, is fixed by stops, and the end of the bar, J, is guided that it cannot be thrown out from between the rollers, and L. At periodic intervals of time, the roller L, is by a rolving cam, M, caused to press the bar, J, against the roller, K′, d at the same time, and actuated by the same cam wheel, M, a atform, N, is lifted till it touches the lower surface of the cheeks, (Fig. 6), and lifts up the bar, J, and causes the roller, K′, of the unter to turn through a space proportional to the amount of rrent passing through the fixed coil, D.

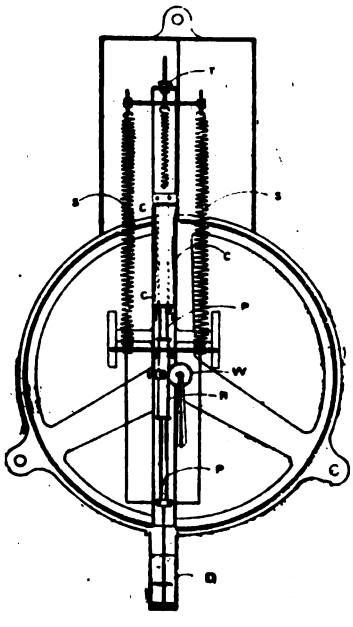

FIG. 8.—Large Dial Voltmeter. Internal Arrangements.

The zero position of the electro-magnet, A, is adjusted so that e extreme end of the bar, J, just touches the platform, N, when e latter is drawn up against the lower surface of the guiding eek, T. The cam wheel, M, is kept revolving uniformly by ckwork, and has attached to it a stud which carries the platform, by a connecting wire, O, having a small spiral spring, O′. As e cam wheel revolves, the platform, N, is lifted till it presses ainst the lower surface of the guiding cheeks, T, and lowered till it is below the lowest possible position of the rod, J, by the rising and falling of the stud, M′. The roller, L, is pivoted to a rod, P, attached to a crosspiece, Q, which is pivoted to the framework of the instrument. Also attached to the crosspiece there is another spring rod, R, which carries a roller, S, which is kept in contact with the cam wheel. While the portion of the cam wheel, which is of larger radius, is passing the roller, S, the roller, L, is pressed forward, and the loose piece, J, is nipped between the rollers L and K′. At this time the platform, N, is at the bottom of its range.

If a current is passing through the fixed coil, D, the electro-magnet, A, and consequently the bar, J, are pulled down by a corresponding amount, and the platform, N, in its upward motion carries the bar, J, back to its zero position, at the same time turning the rolling wheel, K′. When the platform, N, first touches the lower surface of the guiding cheeks, T, the stud on the cam wheel is not quite at its highest position, and while it rises to it the spring, O′, is elongated. When the stud begins to fall the spring contracts, and at the same time the bar J, is unclamped from between the rollers, K′ and L, so that by the time the platform, N, begins to fall, the bar, J, is hanging quite free. When no current is passing, the bar is clamped at its zero position, and the platform, N, on being lifted, touches the end of the bar and the lower surface of the guiding cheeks at the same time, and no record is made on the roller, K.

Description of Large Dial Voltmeter for the Edison Electric Illuminating Company, of New York.

This instrument depends for its action upon the pull of a solenoid, C, on a suspended electro-magnet, P. Fig. 7 gives an external view, and Fig. 8 shows the internal arrangements of the parts. P is a plunger of soft iron about 60 cm. long, and about 1 cm. in diameter, which has a coil of about 30,000 turns of fine wire wound on it. The current is conducted into and out of this circuit by means of two spiral springs, SS, which also serve to support the weight of the electromagnet. The resistance of this circuit is about 1,500 ohms, and it is found that a current of one-twenty-fifth ampere is sufficient to saturate the iron, so that from 60 volts upwards a scale is obtained free from "residual" errors. The electromagnet is suspended, with its upper pole entered about three diameters inside the main solenoid, C, at zero position. T is a screw for adjusting the zero of the electromagnet. Attached to the electromagnet is a rack, R, which is geared into a pinion wheel, W, on a shaft carrying the pointer. When a current is passed round the solenoid, C, the electromagnet is pulled up, and so turns round the pinion wheel and hand. The scale, after the plunger is saturated from 60 volts upwards, consists of equal divisions. A rod, carrying two discs, is screwed into the lower end of the electromagnet, and the discs, working in thick oil in a dashpot, D, serve to damp vibrations due to sudden changes of E.M.F. The diameter of the dial is about 30 inches.

NOTE ON THE COMPARATIVE EFFECTIVENESS OF DIFFERENT TYPES OF LIGHTNING GUARDS.*

BY E. MASSIN.

Electric lines have multiplied tremendously in France on account of the development or creation of numerous telephonic networks, and the proper protection of the apparatus which are used on these lines becomes every day of more and more importance. In the *Annales* for September-October, 1887, and for January-February, 1889, M. Lagarde described a method devised by him for comparing the effectiveness of different types of lightning guards. But although he published the results obtained, M. Lagarde points out the defects of his method. The absolute results are not comparable for different series, owing to "the inconstancy of the batteries actuating the induction coil, variations in the hygrometric condition of the surrounding air, and the other causes that influence the electric charge of a body electrified to such a high potential." A close investigation of the question and a series of preliminary experiments enabled me to see—first of all, that a large induction coil could not without injury furnish continuously for several hours at a time sparks 35 to 40 centimetres long; secondly, that whatever precautions were taken the causes of error indicated by M. Lagarde were unavoidable; and, lastly, that owing to the impossibility of always producing identical charges the classification of the same set of lightning guards in order of merit, frequently varied from one series of experiments to another. It therefore seemed necessary (1) to make use of another source of electricity, (2) to no longer examine how two lightning guards behaved under the action of two identical discharges; but, on the contrary, to compare the simultaneous behaviour of two lightning guards towards the same discharge.

* From the *Annales Télégraphiques.*

Digitized by Google

The Source of Electricity.—A 0·03 ϕ Leyden jar charged by a Wimshurst machine was decided on as a source of electricity. The Wimshurst machine gave sparks of from 0·15m. to 0·20m. under good hygrometric conditions. Owing to the enormous electric pressure employed there were considerable losses in the apparatus composed by the jar and the machine, and to prevent the electricity furnished by the machine from serving after a few turns to merely make good these losses it was as well to make the quantity of electricity furnished as high as possible, and to run the plates of the machine at a high speed. For this purpose three little electric motors arranged in parallel and absorbing 150 watts were employed, giving the plates a speed of 1,200 revolutions. The discharge produced by short-circuiting the jar after a minute's charging produced a spark that appeared to be 8 to 9 centimetres in diameter, and burst with a noise painful to hear. On the other hand, when the jar was discharged through the connections and the experimental apparatus, to be described, the spark was decidedly less violent, and seemed to be only 5 or 6 centimetres in diameter. The conductors employed to make the connections consisted of a cable insulated by a triple layer of gutta-percha. All crossing of the wires was avoided. The wires that connected the jar and the apparatus at certain moments and that were then at an enormous difference of potential, were carried on stretched pieces of string 5 metres long, and were kept at least 50 centimetres apart (*see* Fig. 1). If the conductors were left only a few centimetres apart we heard the crackling of the discharge passing through the pores of the gutta-percha.

Experimental Arrangement Adopted.—In Fig. 2, 1 and 2 were the lead and return cables which came in on to the machine on a large glass tube forming the two branches of a discharger, the handle of which was formed by the glass tube. The positive cable divided at A into the two identical circuits B C D K and B′ C′ D′ K. B and B′ being the two lightning guards to be tested, C C′ being two fused-wire guards protecting the two 500 ohm bells D and D′. The two circuits united at K on the return wire 2. The terminals of D and D′ were connected by "indicators" E and E′, consisting of a plate towards which a platinised screw could be brought up. The head of the screw was divided into 72 equal parts, and the pitch of the screw was about 0·73mm., so that each division corresponded

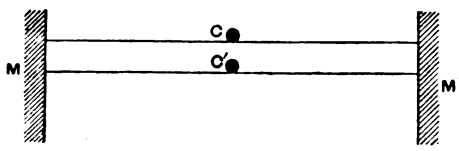

FIG 1

to about 1/100th of a millimetre. It is evident that the larger the quantity of electricity going through D the larger, all things being equal, will be the spark at E. Now, the circuits A B C D K and A′ B′ C′ D′ K are identical, and represent actual installations; if, therefore, the "indicators" E and E′ are properly adjusted the relative values of the sparks at E and E′ will give the relative effectiveness of the two lightning guards B and B′ in respect of the same discharge. To adjust E and E′ the cables 1 and 2 were connected to the poles of a battery, the bells rang, and the screw of E was turned until it came into contact with the plate, when the short-circuited bells were silenced. The screw was then screwed back n divisions. This number n depended on the effectiveness of the lightning guard tested. The same process was gone through for the "indicator" E′, the same number n being chosen. There was now a first approximation, which could be altered if necessary in the course of the experiment.

Mode of Carrying Out an Experiment.—An experiment was carried out as follows:—The jar was charged for a period t; the free ends of the cables 1 and 2 were then suddenly brought up to the coatings, a discharge occurred, and divided itself between the two circuits, part escaping through the lightning guards B and B′, the rest through the bells D and D′ and the indicators E E′. The indicators E and E′ being arranged one beside the other in a dark room, it was easy to determine the relative value of the sparks occurring in them. The circuit was then tested by means of the battery, and the experiment begun over again. If, after a series of discharges, the superiority of the sparks at indicator E, for example, was ascertained, this could only be due either to the inferiority of the lightning guard B or to a faulty regulation of the indicators. To settle the question the lightning guards B and B′ were interchanged, and the superiority passed from indicator E to indicator E′; if not, it was the adjustment that was wrong, and it was modified.

Successive trials always led to the conclusion that the lightning guard connected with the indicator giving the biggest sparks was inferior to the other, since it allowed a larger quantity of electricity to reach the corresponding coils. When the lightning guards to be compared are very good, the indicator has to have a very small gap to allow a discharge to take place, and in some cases it is necessary to have only a gap of 1/100th of a millimetre between the platinised point and the opposite plate. The adjustment of the indicators is a somewhat delicate matter when the lightning guards to be compared are but slightly different, and at times it requires several hours to secure a good adjustment and obtain well-marked results. This method enabled me to obtain identical results at the beginning and at the end of the same day, as well as at different times, so that there is some reason to consider it effective.

Tests were made on air-gap lightning guards—two-plate, two-comb (Bertsch), and plate and comb—on corrugated lightning guards, and on lightning guards with paper, gutta-percha, or mica insulation.

Air-Gap Two-Plate Lightning Guards.—The effectiveness of a lightning guard of this class is independent of its surface, and only depends on the length of the air-gap and on the degree of polish of the plates. It was impossible to discover any difference in the case of two air-gap lightning guards, of which the area of the plates was identical, and of which the area of one was four times that of the other. On the other hand, it was easy to show the inferiority of a lightning guard that had received a certain number of discharges to an identical one, the plates of which had just been polished. For instance, an air-gap lightning guard which had just been cleaned, and had a gap of 73/100ths of a millimetre, was found to be identical with a lightning guard which had already been used and had a gap of only 50/100ths of a millimetre. On polishing the plates of the latter instrument it was necessary to give it a gap of 75/100ths of a millimetre before equivalence was restored.

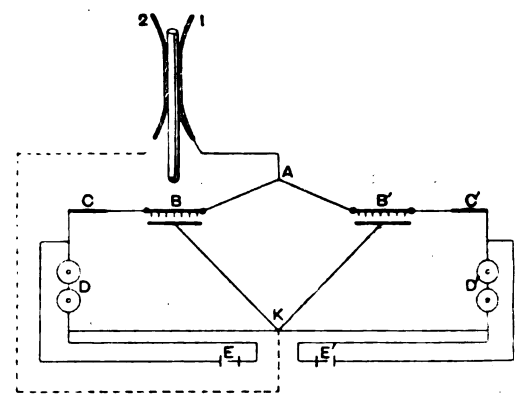

FIG. 2.

As a result of these preliminary experiments the air-gap two-plate protector was taken as a standard of comparison. It was made as follows:—A plate resting on four supports and connected to earth; above it a second plate connected to line, and resting on two set screws, the distance apart of the plates being varied by means of washers (*see* Fig. 3).

Air-Gap Comb Lightning Guard.—With the points 1mm. apart this type is equivalent to a plate protector with a 1mm. air-gap. Equivalence almost holds up to a gap of 8/10ths of a millimetre. For 5/10ths of a millimetre the effectiveness was found to be between that of a plate protector of 5/10ths and 6/10ths of a millimetre. This difference is within the errors of experiment.

Plate and Comb Air-Gap Lightning Guard.—The type tested had a gap of 8/10ths of a millimetre between comb and plate; it was equivalent to a 12/10mm. plate protector. This difference may be explained by the condition of the surface of the plate, which left much to be desired.

Insulating-Sheet Lightning Guard.—With a 7/100mm. sheet of paper, taken from a block of telegram forms, the effectiveness of the protector was the same as that of 40/100mm. air-gap protector. The protection was then very complete, and it was necessary to bring the point of the indicator to within less than 1/100th of a millimetre of the plate to obtain a spark. The paper was perforated at each discharge either by a single hole attaining 3mm. diameter, or by two or three or several holes of less diameter, showing a many-path discharge. It may be useful to note also the difference in the mechanical effects in the case of paper-sheet and air-gap protectors. In the former, one sees well-defined punctures like pin-points surrounded by a brown discolouration. In the latter, one only sees a spot; and it may be asked whether the paper-sheet protector does not deteriorate more rapidly than the air-gap protector under the influence of discharges.

If the insulating sheet consists of paraffined paper, the effectiveness is about the same as if the paraffined paper were replaced by two or three sheets of the same kind of paper having the same total thickness, with a slight difference always in favour of the non-paraffined paper.

Digitized by Google

The gutta-percha sheet lightning-guard of 6/100mm., used by the Telegraph Department, corresponds to an air-gap protector of 170 100mm. If we replace the gutta-percha by a sheet of mica 8 100th of a millimetre thick, its effectiveness is only equal to that of an air-gap plate protector of 200/100mm.

Corrugated Lightning Guards.—In the lightning guards of the Telegraph Department type used in the postmen's call-bell circuits, the planes of the corrugations are 45 100th of a millimetre apart. Such a protector when new is equivalent to a 80/100mm. air-gap plate protector. This lack of effectiveness is due, no doubt, to the state of the opposed surfaces which are not polished.

Conclusions.—The effectiveness of air-gap plate protectors only depends on the distance apart of the metallic plates and their degree of polish. Nevertheless, it is found with this type of lightning-guard that when the gap is only 3/10th to 4/10th of a millimetre the line is put to earth, probably by condensation momentarily short-circuiting the two plates thus brought so close together. The air-gap comb protectors are comparable with the plate protectors. Their construction, it is true, is much more complicated, but

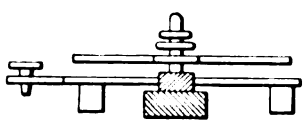

Fig. 3.

they do not seem to be liable to short-circuiting, as mentioned above. Moreover, they have the additional advantage of quietly dissipating, by means of their points, a charge that has not sufficient potential to spark across, a fact which is easily shown to be the case. As to insulating-sheet protectors, it is necessary to eliminate gutta-percha and mica, and to adopt paraffined-paper protectors, the paper being as thin as possible. Paraffined paper is not hygrometric like ordinary paper, and its effectiveness can be made comparable to that of air-gap plate protectors, in which the distance apart of the plates is such that short circuits would be established spontaneously. The sheet of paper ought not to be, it must be pointed out, either softened (*éridé*) or cut (*découpé*); if it is we come back to an air-gap plate protector. Air-gap comb protectors with small gaps or paraffined-paper protectors, are the very ones used in practice, and, as well as in the case of air-gap plate protectors, it is well to point out the defects of the protectors which seem the best. These two kinds have their advantages and disadvantages, the first seems the more thorough and does not require manipulation every time it has been traversed by a discharge, but the second can be installed at much less cost than the first.

ELECTRO-OPTICS.*

BY A. B. BASSET.

The experimental and theoretical investigations of the last twenty years have lent a new interest to what, I venture to think, is one of the most fascinating branches of physical optics, namely, the action of an electromagnetic field upon light. The discoveries which have hitherto been made may be classified under four heads: (1) Faraday's experiments, which show that when plane polarised light is transmitted through a *transparent* magnetised medium, a rotation of the plane of polarisation is produced; (2) Kerr's experiments, which show that the effect of electrostatic force on a *transparent* medium is to convert it into one which is optically equivalent to a uniaxal crystal whose axis is in the direction of the force; (3) Kerr's experiments on the reflection of plane polarised light at the surface of a magnetised iron reflector, which show that a rotation of the plane of polarisation of the reflected light takes place, which in certain cases is in the same and in others in the contrary direction to that of the amperean current, which may be conceived to produce the magnetic force; (4) Kundt's experiments on the reflection of light from magnetised iron, cobalt, and nickel, and also on the transmission of light through thin magnetised films of these metals. There is also another series of experiments by Kundt, in which polarised light is refracted at the upper surface of a plate of glass, is then reflected at the lower surface, and again refracted at the upper surface. The results of these experiments show that the plane of polarisation of the ultimately-emergent light is rotated in the *contrary* direction to that produced by an iron reflector.

There seems to be a fair amount of evidence to lead to the conclusion that Hall's effect is intimately connected with the action of a magnetic field upon light, but further evidence is required before it can be asserted that both phenomena are due to the same ultimate cause. Up to the present time Hall's effect has, I believe, only been detected in conducting media; but if it be assumed to be capable of existing in transparent media, theory furnishes results which, as far as they have been worked out, are in agreement with experiment. Hall's effect is capable of explaining the experiments of Faraday, and it also gives a result in accordance with Kundt's experiments on reflection and refraction from a plate of magnetised glass in the case in which the magnetism and incidence are normal. It would be quite possible to apply this theory to the case of oblique incidence, but the work would be laborious and the final results complicated. The experiments of Prof. Dewar on liquid oxygen would seem to provide a more promising way of testing this theory, for, on account of the high susceptibility of this substance to magnetic action, it is possible that an effect might be observed in the case of *direct* reflection.* According to theory, Hall's effect ought to be positive in the case of glass and gaseous oxygen, and negative in the case of a solution of perchloride of iron; and a repetition of Kundt's experiments, in which the latter liquid is employed in the place of glass, ought to show that the rotation takes place in the *same* direction as that produced by metallic iron. Such experiments would be valuable as a further test of the theory, but they do not appear to have been made.

A Paper recently communicated to the Cambridge Philosophical Society (May 1st) still further confirms the view which I have put forward. In this Paper I have transformed the formulæ for reflection at a magnetised *transparent* medium by assuming that the refractive index is a complex quantity. The resulting formulæ for the amplitudes of the reflected vibrations agree very well with Kerr's experiments so far as qualitative results are concerned, provided the values and signs of certain quantities are supposed to be determined by optical, as distinguished from electromagnetic methods. They are, moreover, the same *as regards their form* as those deducible from Maxwell's theory by taking into account the conductivity combined with Hall's effect; but unfortunately the values of certain constants, when expressed in terms of electrical quantities, differ from the values which are required by optical experiments, in a manner which prevents a perfectly satisfactory electromagnetic theory being constructed in this way, and I doubt whether it will be possible to attain the end in view until a theory based upon the mutual reaction of ether and matter has been discovered in which quantities, upon which the motion of matter depends, enter into combination with electromagnetic quantities.

Although the sign of Kerr's effect in nickel is the same as in iron and cobalt, the sign of Hall's effect is different. This difficulty is apparent rather than real, for a theory based upon the mutual reaction of ether and matter might very well introduce a factor containing the free periods of the vibrations of the matter which would change the sign of the magnetic terms. Some light might be thrown on this point by determining the principal incidence and azimuth for nickel and cobalt.

The generally received theory, that reflection and refraction are materially influenced when any of the free periods of the vibrations of the matter fall within the limits of the visible spectrum, suggests that the sign of Kerr's effect may be different in the case of the ultra-violet and the infra-red portions of the spectrum from what it is in the luminous portion. Experiments on this branch of the subject are needed, and possibly the employment of a fluorescent substance, such as quinine, in the case of the ultra-violet waves, or of a solution of iodine in disulphide of carbon, in conjunction with Prof. Langley's bolometer,† when the infra-red waves are experimented upon, might furnish important information on this point.

The experiments of Kerr on the effect of electrostatic force suggest that if light were reflected from a strongly electrified metallic conductor certain peculiarities would be observed. In the absence of experiments, which do not appear to have been made, it would be impossible to predict with certainty what these effects are likely to be; but it would seem probable that an electrified metallic reflector would behave like a doubly-refracting metallic medium having a *single* optic axis which is perpendicular to the reflecting surface. When light is reflected from the surface of a uniaxal crystal which is cut perpendicularly to the axis, the component vibration at right angles to the plane of incidence is reflected in the same manner as if the medium were isotropic. Under these circumstances we should anticipate that in the case of an electrified metallic reflector the component vibration *in* the plane of incidence would be much more strongly affected by electrification than the component at right angles to this plane. If this speculation should

* From *Nature*.

* The effect produced by a *single* reflection from magnetised glass would be too feeble to be detected; but Dr. Kerr suggested to me that an effect might possibly be observed by employing the method of multiple reflections.

† I do not know whether the bolometer is more sensitive to heat than a pair of average eyes are to light; if it is, experiments on the infra-red waves ought to be easier than experiments on luminous waves.

Digitized by Google

be verified by experiment it would follow that the principal incidence and azimuth, and also the difference between the changes of phase of the two components, would be affected by electrification in a manner which could be observed.

In conclusion, I would point out that further experiments are required of the following nature :-

(1) Experiments on the reflection of light from magnetised *transparent* media, such as glass, perchloride of iron, and also, if possible, from liquid oxygen.

(2) Experiments on reflection from, and transmission through, magnetised metals, special attention being paid to the effects produced by the non-luminous portion of the spectrum.

(3) Experiments on reflection from *electrified* metallic reflectors.

LEGAL INTELLIGENCE.

John Hart v. The National Telephone Company.

On Friday last, in the County of London Sheriffs' Court, Holborn, before Mr. Under-Sheriff Burchell and a jury, the remitted case of John Hart *v.* the National Telephone Company came on for the assessment of damages. This was an action in which the plaintiff, a fruit and vegetable dealer, 13, Wardley-street, Garrett-lane, Wandsworth, sought to recover compensation from the defendant Company for personal injuries sustained through the falling of one of their wires.

Mr. Richard Harris, Q.C., with him Mr. J. W. Moyses, were for the plaintiff, and Mr. Compton Smith appeared for the defendants.

Mr. HARRIS said, in explaining the facts of the case, that the plaintiff was a man in a very substantial way of business. On June 17th he and his son were driving a cart laden with fruit from the market through York-road, Wandsworth. At the corner of a thoroughfare known as Jew's-walk some of the defendants' servants were engaged on the housetops repairing the wires, and suddenly one of the wires fell, catching the plaintiff around the neck and nearly strangling him. The cart was damaged, as was the contents, and the son was thrown into the road, sustaining severe injuries. It was fortunate that the plaintiff's presence of mind did not forsake him, otherwise his head would certainly have been severed by the very thin wire. Feeling that he was being strangled, he immediately dropped the reins and caught the wire, 80ft. of which had fallen, with his hands, and thus saved his life. At the time of the accident it was not thought that the injuries were of a very serious character; but the fact was that the larynx was nearly closed, and the medical men were unable to say whether it would not be permanent. That fact greatly inconvenienced plaintiff in his calling, and, in face of the seriousness of the case, he (Mr. Harris) appealed for heavy damages.

The PLAINTIFF, who was only able to articulate with difficulty, corroborated the opening statement, and, in answer to Mr. MOYSES, said that he bought largely in the London markets, and afterwards retailed the goods to small dealers, who hawked them in the streets on barrows. While he was driving along the York-road he suddenly saw something dazzling in front of him, and felt his neck clasped by a thin wire, similar to the piece produced.

Mr. SMITH severely cross-examined the plaintiff as to the injuries and his earnings.

After medical evidence had been given, Mr. SMITH contended that the plaintiff was in reality a costermonger. In that calling he had to use his voice very much, and by so doing the vocal cords had undoubtedly become thickened chronically. The wire was not blown down violently by a gust of wind, but quietly floated down. His contention was that the injuries were greatly exaggerated.

The jury assessed the damages at £195.

A second action was brought against the same Company by the son, but by consent it was arranged that judgment should be entered in his favour for £60, with costs.

Chelsea Electric Supply Corporation (Limited) v. London Electric Supply Corporation (Limited).

This case came before Mr. Justice Wright in the Vacation Court on Wednesday. Application was made *ex parte* on behalf of the plaintiff Company for an injuction extending over a week restraining the defendants from laying any distributing mains for supplying the electric light within the area supplied by the plaintiffs, except in accordance with the terms of an agreement entered into between the two Companies in July last. There had been correspondence between the parties, and the defendants having on Friday last justified what they were doing, this action was brought.

Mr. MORTON, Q.C., who made the application, on being called upon to explain the urgency of the matter, stated that the plaintiffs might be called upon to supply adjoining owners.

His LORDSHIP granted an injunction over next Wednesday, but intimated that in case the defendants felt that they would be injured by the order they could apply to him to-day in Chambers to dissolve the injunction.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 4, 1893.

The General Electric Company.—General Electric stock reached its lowest point on the Stock Exchange last week, having been sold for 31. Six months ago the stock was worth 117, and during the last two months has dropped about 50 points. The great depression in this stock follows partly from the general business depression in the United States, partly from being classed as an industrial stock—all of which class is now in considerable disfavour—and also on account of inflated capitalisation and the suspicion in regard to the real value of the many million dollars' worth of securities held as assets. At no time has it been thought by unprejudiced observers that the Company was in any serious danger, and that a more favourable view is now taken generally is shown by the continued rise in quotations during the present week. The stock is now selling for 47.

The Edison Lamp Patent.—Since the decision in favour of the Edison lamp patent at Milwaukee renewed interest has been manifested in regard to the date of the expiration of this patent. The opinion seems to prevail that it will expire with the Canadian patent on November 10, 1894. There are several questions, however, bearing on the date which may be carried to the Supreme Court. One of these is in regard to which date shall prevail in the English patent (there are three dates in this patent), another as to whether the law in regard to an American patent expiring with a foreign one previously granted applies to an American; and, finally, whether the date of application or issue of the patent shall hold. The first two issues are considered to have little or no weight. In regard to the third, the decisions of the lower courts have been uniformly against the Edison contention that the date of application instead of issue shall prevail, but as several questions have been overruled by the Supreme Court on interpretations of other points in the same statute, there is a probability that it may reverse the decisions of this question also.

Municipal Electric Lighting.—There seems to be a decided tendency at the present towards towns and cities undertaking the erection and operation of street electric lighting plants. This is particularly marked in the more intelligent districts of the United States and in some of the larger cities in the government of which Americans have yet a voice. In most of the large cities, however, there is little chance of municipal plants being erected, owing to the certainty that political corruption would result.

CORRESPONDENCE.

THE CITY AND SOUTH LONDON AND LIVERPOOL ELECTRIC RAILWAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall be glad if you will allow me to point out, with reference to the comparative figures given in your last issue, that the locomotive and generating expenses per train mile at Liverpool are less than the figure you quote, which is the price paid by the Liverpool Overhead Railway Company to the contractors, who, however, are running the line at an expense which shows a satisfactory margin on this figure, while the expenses in the case of the City and South London are, I believe, the actual expenses incurred in working.—Yours, &c.,

Wolverhampton, August 15, 1893. T. PARKER.

[We pointed out in the Note in question that the figure of 4d. per train mile for locomotive and generating expenses was the contract price.—ED. *E.*]

TRADE NOTES AND NOTICES.

otices for insertion under the above heading must reach the Office ot later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' rectory and Handbook is NOW READY. This useful book contains r 1,000 pages, and several new and handy features have been led. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Com-rison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Gas and Lighting Committee of the lton Corporation invite tenders for the supply and fixing of ernating current transformers. Specifications and forms of nder may be obtained from Mr. J. H. Ryder, the borough elec-cal engineer; and tenders must be sent to Alderman Miles, airman of the above Committee, Gas Offices, Bolton, not later an September 16th. Some further particulars are given in our vertisement columns.

——— The Corporation of Aberystwith invite tenders for the ecution and maintenance of works for the supply of electricity thin the borough, in accordance with the terms of their Pro-sional Order. The conditions, plan, &c., may be inspected at the ices of Mr. A. J. Hughes, the town clerk, to whom tenders ust be sent in not later than September 8th. Some further par-ulars will be found in our advertisement columns.

——— The Dewsbury Board of Guardians invite tenders for hting the workhouse and premises by electricity, which are to in by the 31st inst.

——— The Electric Lighting Committee of Lancaster invite nders for the supply and erection of wrought-iron roofs over the gine and boiler house at their electricity works. Tenders must in by to-morrow (Saturday).

——— The municipal authorities at Dusseldorf invite tenders r the supply and erection of a complete electric lighting and wer plant, which must reach the Oberbürgmeister by 11 a.m. on ptember 1st.

——— The Municipality of Craiova (Roumania) invite tenders the lighting by electricity of a portion of the town. Specifica-ns, conditions, &c., may be obtained from the Secretary to the unicipality, and tenders must be sent in by 2 p.m. on September th (27th).

TENDERS ACCEPTED.—The tender of Callender's Bitumen, Tele-aph and Waterproof Company (Limited) has been accepted by e Richmond Town Council for the supply of the cables and wires the electric fire calls being installed in the borough. The estion of the tenders for instruments and apparatus has been left er for a time.

——— The City of Glasgow District Lunacy Board have cepted the tender of Messrs. Norman and Son, of Glasgow, r the installation of the electric light at their Gartloch Asylum, e amount being £5,628, and that of Messrs. Penman and Co., Glasgow, for three Lancashire steam boilers in connection with e above installation, for the sum of £1,874. 9s. 2d.

——— The Bolton Corporation have accepted the tender of e Brush Electrical Engineering Company (Limited) for the pply of dynamos and alternators for the central station, and that a local firm (Messrs. J. and E. Wood) for the engines. As men-oned in *The Electrician* a fortnight ago, Messrs. Hick, Har-eaves, and Co. have been successful in the tendering for the pply of boilers.

——— The Burton Town Council have accepted the tender of essrs. John Fowler and Company, Leeds (Limited) for the supply an overhead travelling crane for the electric light engine house, a cost of £337; and that of Messrs. Bryan Donkin and Co. fitting furnaces and boilers in connection with the new works, £285.

——— The tender of Messrs. Siemens Bros. and Co. (Limited) s been accepted by the Bradford Corporation for supplying and ing two Willans-Siemens combinations and two switchboards, amount being £3,025.

——— Mr. Thomas Rowbotham, of Coventry-road, Birming-m, is the successful tenderer for the construction of the central ctric light station at Worcester, the amount of his tender being 4,797.

——— The Municipality of Alcalá, Province of Madrid, Spain, rite tenders for the supply of the electric light to the district.

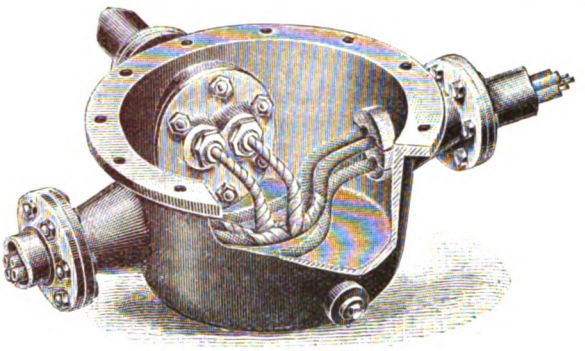
APPOINTMENT.—The Liverpool Watch Committee have appointed r. W. G. P. MacMuldrow electrical inspector for the city.

APPOINTMENT VACANT.—The Town Council of South Shields rite applications for the appointment of a resident electrical gineer to superintend the installation of the electric light in the Borough. Applications must reach Mr. J. Moore Hayton, town clerk, South Shields, not later than 12 noon on August 30th. Further particulars appear in our advertisement columns.

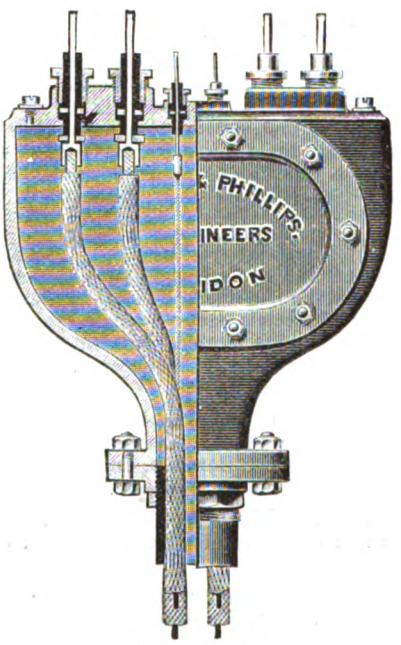
BANKRUPTCY.—Harry Austin and James Myers, trading as manufacturing electricians and electrical engineers at 7, Florence-terrace, Armley, near Leeds, under the style of Austin and Myers, have been adjudicated bankrupts. The first meeting of creditors will be held at the Official Receiver's, Leeds, on August 23rd, and the public examination will take place at the Leeds County Court on September 5th.

EMBEZZLEMENT.—Joseph Francis Chase, aged 50, was charged at the Guildhall on Friday with embezzling, on March 13th last, £2. 10s., received on account of his employers, Messrs. Alabaster, Gatehouse, and Co., Paternoster-row, London. He pleaded guilty, and was sent to prison for three months with hard labour.

MESSRS. JOHNSON AND PHILLIPS.—This firm have just issued some printed particulars with illustrations of their oil insulated underground electric light cables and mains, known as the Brooks system. This system is in use for public lighting at the Royal Observatory, Greenwich, at Brighton, Chatham, Keswick, Rochester, and Hong Kong, as well as being employed on a number of private installations in this country. The illustrations herewith



JUNCTION BOX.



TERMINAL BOX.

show the junction box and the terminal box used in the system, which is no longer in its experimental stage, as is shown by the fact that during the extremely bad weather of last winter the whole of the distribution mains at Chatham, Rochester, and Strood were successfully put down. Each section of the cables used, before being finally connected up, was severely tested with 5,000 volts alternating current, and although the circuit was frequently broken whilst the dynamo was run at this pressure, the mains did not afterwards show any weakness when tested with a sensitive reflecting galvanometer.

MESSRS. W. H. WILLCOX AND CO.—Messrs. Pontifex and Wood (Limited), of Shoe-lane, London, E.C., have transferred their "Farringdon" pump trade, and also the business connected with the "Penberthy" injector and ejector, to Messrs. Willcox and Co., who have purchased the stock of these goods, as well as a large

Digitized by Google

stock of sight-feed lubricators, &c. Printed particulars of the "Penberthy" injector and "Farringdon" pumps can be obtained of Messrs. Willcox and Co., 34 and 36, Southwark-street, S.E., on application.

MECHANICAL STOKERS.—Mr. L. A. Edwards informs us that the Babcock and Wilcox boilers at the Bankside station of the City of London Electric Lighting Company are to be supplied with the patent circular furnace coking stokers, for which he is London agent.

BANDON.—A public meeting of the ratepayers having requested the Town Commissioners to refuse their consent to the granting of a Provisional Order to the Bandon Electric Light Company by the Board of Trade, the matter came before the Commissioners at their last meeting, but a final decision was postponed.

BARROW.—The Barrow Town Council decided, at a recent meeting, after a lengthy discussion, not to proceed with the application for a Provisional Order for the supply of electricity.

BRISTOL.—A dispute has arisen between the Corporation and the Poor-Law Guardians in respect of the assessment of the buildings, instruments, and apparatus used in connection with the electric light supply, which have been assessed at £3,000 gross and £2,000 net rateable value. Against this assessment the Corporation have appealed.

COATBRIDGE.—The Town Council have decided that their new municipal buildings shall be lighted by electricity.

COUNTRY HOUSE LIGHTING.—The contract for the lighting of Old Warden Park for Major Shuttleworth has been entrusted to Messrs. Drake and Gorham. The plant consists of two 10 H.P. fixed boilers to supply steam to two horizontal engines by Messrs. Clayton and Shuttleworth. The power will be available from either engine for driving a workshop. The number of lights is 350.

CHICHESTER.—At the last meeting of the Town Council it was resolved to instruct the Lighting Committee to ascertain whether the Gas Company would in future light the public lamps at a lower rate, having special reference to the lighting of the extended area of the city, and, further, to obtain information as to the cost of lighting the city by electricity, and to report to the Council on the matter generally at an early date.

DUNDALK.—The Electric Lighting Licence which was granted to the Town Commissioners in 1886 expired on July 1st. The Commissioners have made repeated applications for its renewal, which the Board of Trade at first refused to grant, suggesting that the Commissioners should obtain a Provisional Order. After considerable correspondence the Board of Trade have acceded to the application, and have renewed the licence for a further three years.

EDINBURGH.—At a meeting on Monday of the Edinburgh and Leith Corporations Gas Commissioners the question of the charge for supplying gas for the engines to be used by the City Council in the generation of the electric light was again under consideration, and, after some discussion, a motion that the Commissioners offer to supply the Corporation with gas on the same terms as were given to other large consumers was carried.

HARROGATE.—The Town Council at their last meeting commenced the consideration of the tenders which had been received for supplying electric light to the Borough, and, after some discussion, final decision in the matter was postponed.

JERUSALEM.—The Municipality of Jerusalem have under consideration plans and estimates for the installation of the electric light in the City.

KILLARNEY.—At the last meeting of the Town Commissioners it was decided to invite tenders for the public lighting of the town by electricity.

LINCOLN.—The Corporation have received a notice from the County of London and Brush Provincial Electric Lighting Company that it is intended to apply to the Board of Trade for a Provisional Order to authorise the supply of electricity within the city.

PAISLEY.—It being proposed to build a new hospital at Darnley, near Paisley, it has been decided that it shall be lighted by electricity, and Dr. J. T. Bottomley, of Glasgow, has been requested to report on the matter, and to submit a detailed specification, with estimate of cost.

STONEHOUSE.—The Local Board at their last meeting adopted a recommendation of the Town Hall Committee that the building be supplied with electric light at a cost not exceeding £500.

TAUNTON.—The Local Government Board have granted the Town Council a loan of £15,000 for the purpose of electric light works, repayment of principal and interest to extend over 25 years.

THE ELECTRIC LIGHT IN PAPER MILLS.—The works of the British Paper Company (Limited), Frogmore Mill, Two Waters (Herts.), have been recently fitted with the electric light. The work has been carried out by the London and Lancashire Electric and General Engineering Company (Limited), of Dalston. One of the features of the installation is the improved system of water-tight mains, joint boxes, and lamp fittings, which have been specially designed by Mr. C. N. Russell, the engineer and manager, with a view to resisting the effects of steam and moisture incidental to all paper mills. 16 c.p. incandescent lamps are used throughout the whole of the various departments, whilst a special arc lamp of 2,000 nominal c.p., intended for use in colour testing at night-time, is fixed in the beater house.

WHITEHAVEN.—The Harbour Trust have decided to light the harbour by electricity, and have agreed to an arrangement come to between the Harbour Committee and the Electric Lighting Committee.

WYNBERG (SOUTH AFRICA).—The central electric lighting station, which has been constructed by the Cape Town and Suburban Electric Lighting Syndicate (Limited), was opened on the 22nd ult. The installation consists of two Kapp dynamos by Messrs. Johnson and Phillips, working at a pressure of 130 volts each, and a storage battery plant consisting of 120 D.P. cells, which are capable of supplying 300 lamps for nine hours without the aid of the machinery. Ninety-nine 20-c.p. lamps and one 100-c.p. lamp take the place of the 60 oil lamps which were formerly used in the streets of Wynberg. The current is likewise supplied to business premises, places of worship, and residences.

YEADON.—The Local Board have had under consideration a scheme for an electric light installation, the cost of which is estimated at £3,500. The annual revenue is estimated at £750, and the working expenses at £540. It was resolved to apply to the Board of Trade for a licence empowering them to undertake the supply of electricity for lighting purposes.

PATENT RECORD

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

July 18, 1893.

13,888. C. WIESE. Canada. Improvements in electric current and current generator governors.

13,889. J. SHELL BOLTON and T. J. MURDAY. Newcastle-on-Tyne. An electrical self-winding clock.

13,900. R. G. BENNETT. London. Improvements in electric heating.

13,911. W. P. THOMPSON. Liverpool. An improved method of, and apparatus for, heating, welding, or working metals electrically. (Charles Lewis Coffin, United States.)*

July 19, 1893.

13,976. THE LONDON ELECTRIC WIRE COMPANY (LIMITED) and H. CAPEL. London. Improvements in dynamo brushes.

13,992. O. R. KNORR, C. SCHREIBER, and F. O. FISCHER. London. Electrical perforating or "pricking" device suitable for making tracings or stencils.

13,995. F. E ELMORE. London. Improvements in apparatus for the manufacture electrolytically of tubes and other articles of circular section.

13,996. F. B. BEHR. London. Improvements in vehicles and electric locomotives for single-line elevated railways.

14,000. S. Z. DE FERRANTI. London. Improvements in and relating to electricity meters.

14,003. A. A. GOLDSTON. London. Improvements in or connected with electric circuit-closing devices for series circuits.

14,012. H. BONNER. London. Improvements in electric batteries.

July 20, 1893.

14,030. B. THOMAS BOWDON. Improvements in apparatus for the suspension of electric light fittings.

14,056. W. H. LONGSDORF. London. Improvements in electrolytes for primary batteries.

14,076. H. H. LAKE. London. Improvements in electric measuring instruments. (A. H. Armen, United States.)*

14,087. H. H. LAKE. London. Improvements relating to incandescent lamps. (The General Electric Company, United States.)

11,143. Dorman and Smith. Electrical switches, &c.

11,622. Sanders and Thompson. Magnetic separation.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Company (Limited).

The forty-fourth ordinary general meeting of this Company was held at the offices, 58, Old Broad-street, on Wednesday last. The chair was taken by Mr. Thomas Greenwood.

The SECRETARY (Mr. James Scott) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I apprehend that you have already made yourselves acquainted with the contents of the report and accounts, which although nominally presented to day, have been in your hands for a week, so it will therefore be unnecessary to read them again. Indeed, I should not be at all surprised, seeing that our accounts are so similar from half-year to half-year if you almost knew them from memory. There are, however, one or two salient points which I should like to bring to your notice. The first is that there has been an improvement in the total receipts of upwards of £600, comparing those of the past half-year with those of the corresponding period of the previous year; and the working expenses have been less, taking the same periods for comparison, by £562. We therefore have an improvement of £1,164, which goes to swell the balance carried forward to next half-year, which is about £1,167 more than we carried forward 12 months ago. The reserve which has been made this half-year has been precisely similar in amount to that which we made 12 months ago, but we have divided it this time, carrying £1,500 to a reserve against any loss that may arise from the failure of banks, and £5,500 to the general reserve fund, whereas in the former period we carried the whole £7,000 to the credit of the reserve fund only. I do not think we shall make a great loss by the banks, but it is always well to err on the safe side, and it is well also to strike the iron while it is hot, and to make hay while the sun shines. Our half-year is sufficiently good to make the reserve, and, therefore, to be quite sure that we have an ample reserve for such a purpose, we have carried that £1,500 to the credit of that account. You are aware that a considerable number of banks, especially the Australian ones, have gone into liquidation, and that as we divided our deposits over a large number of banks we necessarily have a considerable number of them upon our list of defaulters, although the amounts deposited with each are comparatively small. Those in the list abstract C have been reconstructed, our deposits with them amounting in all to £24,000, and I have no reason to doubt that, with the time afforded to these banks, when these deposit notes fall due, a great majority of them, at any rate, will be honoured at the dates fixed. There is, however, one item—I was going to say in the accounts, but it is not in the accounts, and is conspicuous by its absence—that is, the charge for the annual payment for the purchase of the cable which was laid in 1881 between Cienfuegos and Santiago. That payment has been completed, and we have no further charge to make in our accounts. I do notthink there is any other thing that calls for notice, but if shareholders desire any further information we are at their disposal. The resolution that I have to propose is as follows:—

"*That the report and accounts for the half-year ended June 30th last, now submitted, be received and adopted.*"

Mr. CHARLES W. PARISH seconded the motion.

The Rev. JOHN WILLIAM BROWN: Mr. Chairman and gentlemen, we are a very small number here to-day, so far as shareholders are concerned, and I take it, Mr. Chairman, that that is a compliment to yourself and your co-Directors, signifying the complete trust which we as shareholders have in our Board. I should have liked to see more shareholders present, but I suppose the excessive heat of the weather has rather frightened them. However, as there are one or two items of special interest in the accounts laid before us, I made up my mind to brave the heat and to attend the meeting. I am very glad to hear our good Chairman assure us that due provision has been made in the accounts for any loss the Company may suffer owing to the unfortunate liquidation of the Australian banks. I must say that at the time when the news came concerning the financial storm in Australia, when I knew that some of our banks were affected, it filled me with considerable alarm; but I felt the utmost confidence that our Board would do their very best to steer this ship through the storm, and I believe that they have done so in the way which has just been explained to us, by putting £1,500 to reserve to meet any contingent losses. Our Chairman mentioned the sum of £24,000, but I could not quite catch the meaning of his remark. To what did that £24,000 refer? What are the banks alluded to? Did the Chairman mean to say that that £24,000 was rather doubtful? I should like a little further light thrown on that point. Then, with respect to the reserve fund, it has now reached £100,000, and I have always been given to understand that when the reserve fund reached that amount no further sum would be taken from revenue account year by year to increase it. I should like our Chairman to give us a word or two as to what is in his mind and in the minds of his colleagues as to what is going to be done with the reserve fund. In what way will the shareholders benefit by the fact that the sum has reached £100,000, and that it is not proposed to increase the amount? Then, will the Chairman enlighten us by giving us any further information, if he has any, about the lawsuit?

Mr. W. GRIFFITH: Looking over the report and balance-sheet I came to somewhat the same conclusions as the previous speaker, but it struck me rather forcibly that it would be much more pleasant, instead of increasing our reserve fund, to divide it among the shareholders, the more especially as our reserve fund is not altogether in a satisfactory state. We find that we have put our money into bags with holes in them—that these Australian banks are willing enough to receive our money, but unfortunately, they do not keep it safely. I am afraid, looking at the form of the accounts, that we are to take the £1,500 put to reserve on account

Digitized by Google

of the banks as a real loss. You add up the items of the investments and then deduct the £1,500 as if we really could not count upon the whole sum, except minus this £1,500. It was wise and prudent to put that amount aside, because no balance-sheet is worth anything unless it puts a proper value on doubtful debts and bad investments. There was one point, however, which struck me, on which, perhaps, you would give us some information, although you may have done so already, as I regret that I was a little late in arriving at the meeting. I mean with respect to the intention of the board to lower the rates for messages. If there is competition that may be absolutely necessary, but in a small company like ours I think it is wisdom to make as much as we can out of our plant. In a large company like the Anglo-American, where the business comes in in large volumes, it may be wise to charge small rates, but in a Company like ours—certainly a most successful one—we have not these large amounts, and it seems to me that the way is to make as much as we can out of our plant. At the same time, I admit that you have superior information, and there may be competition which we must meet by lowering our rates. I would also reiterate one of the remarks of the last speaker, and ask you if you will kindly inform us what is to be the ultimate fate of our reserve fund. It is a most beneficial thing that it may be used to equalise dividends. That is always in favour of putting a large sum thereto, but it creates a little doubt in our minds. You talk of equalising the dividend in the future, as if you anticipated a stormy and unpleasant period of business in the next 12 months. I hope, however, that you will be able to reassure us, and tell us that we have not much to fear, and that we may hope that our business will keep up, and that we shall receive the same large and pleasant dividend as regularly and as punctually as before.

The CHAIRMAN: Does any other shareholder wish to put any questions? If not, I will answer these. Replying to Mr. Brown, as to which banks are included in the £24,000, please take abstract C in your hands, and include the whole of the banks there with the exception of the Colonial Bank of New Zealand, £1,000, which falls due in November next, and which we shall doubtless receive. Without enumerating them you will find them all in abstract C. All the banks there mentioned, with the exception of the Colonial Bank of New Zealand, have been or are in liquidation, and we shall have to wait for our money for several years. Meantime, however, we shall—and we have up to the present time—received our interest, and I see no reason for that being reduced or not paid. The Australians have gone through very trying times, but I think that the form in which the present companies are arranged will give them such a strong position that they will be in a more flourishing condition after their reconstruction than they were before. They were liable for large amounts of money before, payable at different dates, and early dates, too. Now, by the re-arrangement, all these payments are postponed, and the banks stand practically in the position of new institutions with fresh capital to go on with their business. I have very great faith in Australia, and in the five years' time that has been given I have great hope that we shall receive our money; but, as I explained before Mr. Griffith arrived, we thought it would be better to err on the safe side, and as we had a considerable sum of money this half-year, we thought it was wise to make this provision, which we can afford to do. As regards the reserve fund, you must remember that our cables are not new. One of them was laid in 1870, and is therefore 23 years old. That is the line between Cienfuegos and Batabano. The other part of that line, laid at the same time, between Cienfuegos and Santiago, has been long since abandoned. In 1875 another cable was laid between Santiago and Cienfuegos, which, therefore, is 18 years old. Another was laid in 1881 between the same two points, and is therefore 12 years old. We have one cable almost new, between Cienfuegos and Batabano, it being only two years old. Regarding the 23 years' old cable, it is not improbable that we shall have to replace it, which may make a considerable dip into our reserve fund. I quite agree with the proprietors who have spoken on the subject that a reserve fund of £100,000 is large, but I do not think it is too large, having regard to the facts which I have mentioned, of the age of our cables, and to the fact that we may have to come into competition, and to reduce our rates. As regards the reduction of rates, it is not the intention of the Directors to make any reduction until it is necessary, nor until we see that it is entirely to benefit us. We must look ahead, and I can only say that negotiations are pending with a view to a reduction of rates. Although these arrangements are not completed we thought it only right to let the shareholders know that they were in contemplation, but we shall not make any reduction until it is necessary to do so. I think I have said as much as I ought to say in a meeting of this kind, because, as you know, our report is printed and circulated, and our foes can read it as well as our friends. The lawsuit has been pressed and will be pressed; and I think it is time now to get it carried through as quickly as possible. We are doing all we can to get a decision, and we have very great hope that it must necessarily be in our favour. I think I have answered all the questions. If not kindly remind me of any I have omitted.

The resolution, that the report and accounts be adopted, was carried unanimously.

Mr. George Keith was re-elected a Director, and Mr. John Gane an auditor, and a vote of thanks to the Chairman having been passed, the proceedings terminated.

International Electric Subway Company (Limited).

On Thursday, last week, the first ordinary general meeting of this Company was held at 72, Bishopsgate-street Within, E.C. Mr. John L. Martin in the chair. The following note of the proceedings has been forwarded to us:—

The SECRETARY having read the notice convening the meeting, the CHAIRMAN said that "since the statutory meeting held last year two contracts for supplying the Johnstone system of conduits have been carried out; one for the City of London Electric Lighting Company, who laid about a quarter of a mile of the conduit in Blackfriars. The types used were the nine-way and the six-way, each duct or way measuring 2½ in. square. It will be readily understood that as this was the first time the conduct had been laid in England it was a most important moment for this Company; it is therefore a matter for congratulation that the work done was perfectly satisfactory, the top and bottom troughs exactly fitting together, and when the conduit was keyed up it made a solid structure. It may be mentioned that no skilled labour is required, and no special tools for laying the conduit. In fact, a great deal of the work can be done by boys; in this way the cost of laying is much less than where separate pipes are used; each pipe would cost 6d. per yard run to lay and joint, whereas 9d. per yard run covers the cost of laying and jointing the nine-way conduit. Some of the conduit has also been supplied to the Keswick Electric Lighting Company (Limited), and their engineer was so much pleased with it that during the last few days he has ordered more with handholes for making house connections. During the last month we have obtained the contract for all the underground mains at Portsmouth. The types used will be a three-way and a two-way; each duct will measure 2½in. square, and the house connections will be made by means of the handholes, which are a special feature of the system. The amount of the contract is £12,000, exclusive of accessories. The work will be commenced in about a fortnight's time. It is most important that the conduit is to be laid in a well-known town like Portsmouth, for there its many advantages will be seen and understood in a way which is impossible where only a short piece of conduit is laid. The Company still owns the patents for France, Austria, Belgium, and Italy, as it has not been thought advisable to dispose of these until a large contract had been obtained in England. Negotiations are now being entered into for working some of the foreign patents on a Royalty." The Chairman concluded by moving the adoption of the report and statement of accounts.

The motion was seconded and carried unanimously.

A cordial vote of thanks was then passed to the Directors, and to the Managing Director (Mr. Margesson) for the zeal he had shown in promoting the interests of the Company, after which the proceedings terminated.

Oriental Telephone and Electric Company (Limited).

The following report of the Directors for the year ended December 31, 1892, will be presented at the thirteenth ordinary general meeting of the Company, to be held at the Cannon-street Hotel, London, on Wednesday, August 23rd, at 1 p.m.:—

As mentioned to the shareholders at the last annual general meeting, an appeal was lodged by Mr. Ness against the decision of Mr. Justice Kekewich in the matter of the declaration and distribution of the previous dividend. The Court of Appeal having reversed the judgment of Mr. Justice Kekewich, the Directors had no alternative but to submit the case to the House of Lords for a final interpretation of the Agreement with the vendors. The annual meeting has consequently been delayed pending the result of this appeal. Judgment was given by the House of Lords on the 27th ult., which allowed the appeal and upheld the decision of Mr. Justice Kekewich. The dividends, therefore, falling to the Vendor shareholders, have to be paid over to the Ordinary shareholders until such time as the arrears of interest due to the latter for the first five years after the incorporation of the Company have been satisfied. These arrears, after payment of the last dividend, amounted to about £13,000.

The revenue account for the year shows a balance to credit of £9,035 5s. 11d., which has been transferred to Profit and Loss, and including £1,957. 16s. 4d. brought forward from 1891, there remains a balance for disposal of £11,043. 2s. 3d. The Directors propose to deal with this as follows:—To write off £251. 13s. 6d. for legal expenses, £77. 10s. 4d. being 50 per cent. of the Company's claim on the liquidators of the New Oriental Bank Corporation in respect of a balance at Mauritius; £533. 15s. 4d. in reduction of capital expenditure; to transfer £2,500 to reserve; and to pay a dividend at the rate of 2½ per cent. on the total paid-up capital of the Company, free of income-tax, carrying forward £3.191. 10s. 10d. This dividend, together with that declared on the Vendors' shares and applied to the Ordinary shares, amounts to £3. 12s. 2d. per cent. on all Ordinary shares issued prior to February 4, 1886.

Although the balance of revenue account shows but a small improvement over the previous year, there has been a considerable extension of business at every agency, including those of the subsidiary companies. The remittances and dividends, however, received from the East are, with the exception of Egypt, the equivalent of a silver currency, and, but for the further decline in the value of that metal during the year, the revenue account would have shown a more favourable result. The Bengal Company has paid a dividend of 6 per cent., and the Bombay Company one of 4 per cent. for the past year, the last-named company again applying Rs.10,000 to reserve and depreciation instead of increasing its dividend. Notwithstanding that the Directors of the Telephone Company of Egypt report that one of the late officials of that Company had been guilty of grave irregularities, they have been able, after payment of debenture interest, to distribute the usual dividend of 6 per cent. on the Preferred shares, to write off £426. 7s. 4d. for depreciation, and to carry forward £1,446. 7s. The China and Japan Telephone Company closed its accounts for the past year with a surplus on revenue account of £549. 15s. 7d., after payment of debenture interest; the Directors of that Company, however, in view of currency contingencies, did not recommend a dividend, but applied the amount in part towards the reduction of capital expenditure and depreciation of stores, carrying forward the balance.

Digitized by Google

The court has finally approved the amendment of the Company's memorandum of association as sanctioned by the shareholders, and the name of the Company is now registered as The Oriental Telephone and Electric Company (Limited).

The Directors to retire at the present meeting are Messrs. G. B. Frost and B. St. John Ackers, both of whom, being eligible, offer themselves for re-election. The Auditors, Messrs. Deloitte, Dever, Griffiths, and Co. also offer themselves for re-election.

Brush Electrical Engineering Company (Limited).

The following is the Directors' report, to be presented to the shareholders at the general meeting to be held at Cannon-street Hotel, London, E.C., on Thursday next, August 24th, at 3 p.m. :—

The profit and loss account for the year ended June 30, 1893, shows a gross profit of £50,158. 6s., including the amount brought forward from last account, to which must be added £3,150. 12s. 2d., the balance of premium after payment of expenses arising from the additional Preference and Ordinary shares issued during the year. After deducting standing charges, maintenance of buildings, plant and patents, interest on debenture stock, and the whole cost of concentrating the Company's works at Loughborough, amounting to £1,328. 11s. 2d., there remains a balance of £26,394. 12s. 9d to be dealt with. After providing the full dividend on the Six per Cent. Preference shares for the year, and an interim dividend at the rate of 5 per cent. per annum, which has already been paid on the Ordinary shares for the half-year ended December 31, 1892, the Directors recommend that the whole amount standing to the debit of preliminary expenses account, amounting to £1,575. 2s. 3d., be written off; and that a further dividend at the rate of 7 per cent. per annum be paid on the Ordinary shares for the six months ended June 30, 1893, leaving £815. 5s. 3d. to be carried forward.

The capital account has been increased during the year by the issue of 15,000 Six per Cent. Preference shares, and 11,617 Ordinary shares, which have been fully subscribed. During the year the sum of £10,681. 19s. 10d. has been expended on capital account, chiefly in additional plant and buildings at Loughborough, and further extensions of the Company's works there are still in progress. These extensions have been rendered necessary by the increasing volume of central station plant which the Company are being called upon to manufacture.

Good progress has been made with the construction of heavy plant for the Bankside station of the City of London Electric Lighting Company, the dynamos for which are each capable of supplying current for 15,000 glow lamps of 8 c.p. The first two of these are now delivered, and four more are in course of construction at Loughborough.

During the past year the Directors have concluded a satisfactory arrangement with the Otis Elevator Company, of Mansion House-buildings, E.C., for the manufacture at the Loughborough works of the elevators and other appliances required by them. In view of the growing demand for electrically worked lifts, arising from the introduction of electric supply into the leading towns of Great Britain and elsewhere, it is thought that the step which has been taken will prove of increasing advantage to your Company in the future.

The home business of the Company generally continues in a healthy state; and the expiry of the Edison master glow lamp patent next November will probably give an additional impetus to central station development. Your Directors have made arrangements to resume the sale of glow lamps of their own manufacture as soon as the above Edison patent expires.

The Australian branch of your business has naturally received a severe check owing to the late financial crisis in the Colonies, but your Company has sustained no loss through any of the bank failures which have taken place. In Austria your business shows a steady growth, and the factory is kept fully employed on Continental orders. During the year the Municipality of Temesvar has purchased your central station there. The amount thus received has been deducted from the property accounts of your foreign and Colonial branches, a separate balance-sheet of which is subjoined as usual.

The outlook for the current year is good. Your works are at present fully employed, and fresh orders are coming in well; whilst in the coming year the full benefit of the economies anticipated from the concentration of the Company's manufacturing operations at Loughborough should now be felt. It is believed that these economies will prove sufficient to provide the dividend upon the last issue of shares.

The Directors deeply regret to record the loss by death of the late Chairman, the Duke of Marlborough. The active interest he displayed in all questions affecting the electrical industry causes his loss to your Company to be the more keenly felt. Mr. J. B. Braithwaite has been elected Chairman in his place. Mr. E. Garcke has resigned his position on the Board, and, subject to the confirmation of the shareholders at the general meeting, Mr. Arthur Ayres has been elected to succeed him. Messrs. J. B. Braithwaite and B. H. Van Tromp retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also retire and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

G. E. BELLISS AND CO. (LIMITED).—This Company was registered on August 11th with a capital of £150,000 in £10 shares (of which 10,000 are Ordinary and the remainder 6 per cent. Cumulative Preference), to execute and carry into effect an agreement between George E. Belliss and Alfred Morcom, of the one part, and the Company, of the other part, for the sale to and purchase by the Company of the business of engineers and boiler makers carried on by the said Messrs. Belliss and Morcom under the trade name of "G. E. Belliss and Co.," at the Ledsam-street Works, Birmingham, and to carry on the said business, and also that of electricians, electrical, mechanical, and general engineers, engine manufacturers, suppliers of electricity for the purposes of light, heat, motive-power, or otherwise, and manufacturers of and dealers in all machinery, apparatus and things required for, or capable of, being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The subscribers (with one share each), are :—G. E. Belliss, Mrs. G. E. Belliss, and Miss T. E. Belliss, "The Dell," King's Norton; A. Morcom and Mrs. A. Morcom, "Trelawne," Augustus-road, Edgbaston; Thomas Simpson, 6, Waterloo-street, Birmingham; G. B. Parrott and T. H. Parrott, 21, Duchess-road, Edgbaston; and J. Belliss, 64, Francis-road, Edgbaston. The first Directors are: George E. Belliss, Alfred Morcom, and Albert E. Seaton.

GARDINER, SONS, AND CO. (LIMITED).—The Company was registered on August 10th with a capital of £80,000 in £10 shares, to carry on as a limited Company the business of ironmongers, iron merchants, mechanical, electrical, and general engineers, machinists, iron and brass founders, &c., carried on by John Gardiner and Thomas C. Gardiner, under the trade name of "Gardiner, Sons, and Co."

NEW BRITISH ELECTRIC INSTALLATION CONTRACTORS (LIMITED). This Company, which is a reconstruction of the British Electric Installation Contractors (Limited), of Worcester, has entered into an agreement with the latter, by which the old Company has sold it business for £3,000, payable in £6 per cent. Mortgage Debentures of the new Company, redeemable in seven years from March 5, 1893, the purchase taking effect as from February 1st.

NORWICH ELECTRICITY COMPANY (LIMITED).—The annual return for 1892, made up to December 31st, was not filed till July 8, 1893. The nominal capital is £50,000, in £10 shares, of which 1,774 have been taken up. £8 per share has been called, resulting in the payment of £14,226. 10s. (which includes amount paid in full on 36 shares), leaving £37. 10s. in arrears. The usual return for 1893, made up to July 1st, was filed on the same day as the foregoing, when the full amount had been called on each share taken up, £16,382. 10s. being paid, leaving £857. 10s. as yet unpaid.

PACIFIC TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to May 24th, has been filed. 18 shares, out of a nominal capital of £2,000,000, in £10 shares, have been taken up, and the full amount has been called, resulting in the payment of £130, leaving £50 in arrears. It is stated that no business is being done by the Company. The shareholders include the Countess of Milltown, Sir J. P. Corry, Bart., M.P., Sir Daniel Cooper, Bart., the Earl of Radnor, J. Henniker Heaton, M.P., Sir W. J. Clarke, Bart., Sir S. Wilson, M.P., Sir Donald Smith, K.C.M.G., Sir Sandford Fleming, C.M.G., and others.

RIVER PLATE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to May 22nd, was recently filed. The nominal capital is £500,000, divided into 49,900 Ordinary shares of £10 each, and 1,000 Founders' shares of £1 each, of which 13,557 Ordinary and 892 Founders' shares have been taken up. 2,400 of the former have been issued as fully paid, while the full amounts have been called on the remainder. The calls paid amount to £110,892, while a sum of £1,570 is unpaid.

SCOTTISH HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to June 30, 1892, was filed on July 17, 1893. As no meeting has been held and no business carried on, only the seven signatories' shares out of a nominal capital have been taken up and no calls made.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The first annual return of this Company, made up to and filed on July 27, 1893, shows that out of a nominal capital of £98,000, divided in 14,000 shares of £7 each, 4,000 shares have been taken up, which were issued with £5 considered as paid on each. A call of £1 per share has been made, which, with the exception of £5, has been paid.

SIEMENS BROTHERS AND CO. (LIMITED).—The annual return of this Company, made up to July 11th, has been filed. The whole capital of £500,000, in shares of £100 each, had been taken up, and a call of £85 per share made, and £425,000 paid in respect thereof.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended August 13th were £825, as against £721 for the corresponding period of last year, being a increase of £105. The total receipts for the half-year amount to £5,051, against £4,661 in the corresponding period of 1892, being an increase of £390.

DIRECT SPANISH TELEGRAPH COMPANY.—This Company, notifying the interruption of the Falmouth-Bilbao Cable, announce that arrangements have been made by which telegrams for Bilbao, Madrid, and other places in Spain can, during the interruption be promptly forwarded by the Eastern Telegraph Company's route. Telegrams will be received at the Direct Spanish Company's stations, 74, Gracechurch-street, and 280, Winchester House, E.C., and at the Eastern Telegraph Company's stations in London, Liverpool, Manchester, and Glasgow.

KNIGHT AND CROWTHER (LIMITED).—At the second annual meeting of this Company held last week dividends of 6½ per cent. on the Preference shares and 5 per cent. on the Ordinary shares were declared.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 797.—Vol. XXXI. FRIDAY, AUGUST 25, 1893. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

A Paper was read on Tuesday last by Prof. S. P. Thompson before the Electrical Congress at Chicago, on "Ocean Telephony." Mr. Oliver Heaviside has written on this matter on more than one occasion, and by a coincidence, deals with it in our present issue. Prof. Perry recently contributed a rather abstruse Paper to the Physical Society on it, and on January 6th we called attention to the subject and gave an abstract of Prof. S. P. Thompson's first patent. Mr. Preece also has turned his attention to this problem but on different lines. The present Paper, the first half of which will be found in another column, gives the theory in very simple language, and contains a number of suggestions for putting the method into practice. Neither practical directions for the design and construction of cables for submarine telephony are given, nor does the author concern himself at present with practical considerations affecting the volume of traffic, the hours of working, and other commercial considerations. Whether such a cable if ever laid across the Atlantic would be more useful for telephony or, for high-speed working at 400 words or so per minute, need not here be discussed. It must, of course, be remembered that for securing continuity of service duplicate, if not triplicate, cables are necessary, quite apart from the double or three-fold carrying capacity; and a single cable carrying ten times the traffic would by no means replace the ten cables which are now at work in the North Atlantic. Meanwhile, the problem, from a scientific point of view, is of the highest interest, and both cable men and telephone men will have to give it careful consideration.

We print, this week, a detailed account of experiments on the use of a magnetic shield for preventing appreciable disturbance of the magnetic instruments at Greenwich by the stray field of a dynamo. There are several points of considerable interest in these experiments. The action of one magnet on another is generally treated from the magnetometer point of view in text-books, the length of the deflecting magnet introducing a little complication. But when the distance of the deflected magnet is large compared with this length, and the deflections are small, the deflecting force is approximately inversely as the cube of the distance. This was confirmed by the experiments. The effect of this shield, though on a small scale, is interesting in connection with the disturbances likely to arise in connection with electric railways. Though the dynamo gave only two kilowatts, the observing instrument, a Kew unifilar magnetometer, is extremely delicate. The final result, a deflection of only half a second of arc of the declination magnets in the Greenwich Observatory is very satisfactory.

One of the advantages of the State administration of the postal and telegraph services is that the regulations can be cast into a uniform shape, and are easily accessible. Were the post office and telegraphs, like the railways, parcels delivery companies, and telephones conducted by private enterprise, while we might gain much by competition, we should lose in simplicity. The "Post Office Guide" is a book which requires a good deal more knowledge to use than the so-called "Post Office Directory," but it is distinctly less complicated than Bradshaw. A rather indignant letter to *The Times* last week reveals a deficiency in this useful publication. Somebody wanted to send a telegram on Sunday, and was informed that the telegraph office at the destination was closed. The postal officials were apparently unable to tell him the name of the nearest town, where the telegraph office was kept open to the later hour, nor *a fortiori* the porterage from this unknown town to the destination. The writer, thereupon, asked for a map, and the theme of his loud complaint is that no map showing the telegraph stations is in existence. The British Government does not distinguish itself in map-making, and a little reflection shows that a county atlas rather than a map would be wanted, as the difficulty arises in connection with the smaller towns and villages.

The "Post Office Guide" gives a list of all villages having any kind of post office, together with the name of the nearest delivering telegraph office, and its distance in miles. Near the end of the book, as though a protest against Sunday work, is a list of the offices which are open beyond the usual hours on Sundays, or are open always. But if the sender of a telegram, looking up the nearest telegraph office to his village does not find it in this Sunday list, there is no more information for him. All that is wanted is the addition to the first list, of the name of the nearest telegraph office open on Sundays to a late hour, with its distance. There are only nine offices in London, twenty-two in the rest of England, five in Scotland, and five in Ireland, open always. *The Times* thinks that it would be "perfectly easy to make arrangements whereby it should never at any time, night or day, Sunday or week-day, be impossible for any one office in

Digitized by Google

the Kingdom to gain the attention of any other office." The first arrangement that suggests itself is a gun, semaphore and rocket apparatus on the top of each country post office, a rule that the telegraph operator shall never take a Sunday afternoon walk out of earshot or sight of the said apparatus, and that the sender shall pay a fee to be handed to the said operator as compensation for spoiling the said Sunday afternoon walk.

THE opposition of the Leicester Ratepayers' Association to the proposed municipal electric lighting undertaking, which at one time appeared to be meeting with considerable support, scarcely justified its existence at the Local Government Board inquiry, held on Friday last. On the other hand, if public opinion be in reality in favour of municipalising anything and everything, then no particular harm can come from dropping once and for all the old bogey of huge purchase-price that will one day have to be paid to private monopolists, unless electric lighting is straightway municipalised. Thus in his address to the Inspector, the Town Clerk of Leicester justified the step contemplated by the Town Council by "the experience they had already had in Leicester in reference to private companies," and instanced the 116 per cent. premium paid to the Gas Company, and the 97 per cent. premium paid to the Water Company for compulsory purchase. Such an argument from the past is, in face of Section 2 of the Electric Lighting Act of 1888, entirely beside the point. According to an eminent authority, the result of Section 27 of the Act of 1882, which is, in principle, the counterpart of its successor in the later Act, will be that those private capitalists who embark in an electric light undertaking will, on the one hand, run all the risks of failure of every kind and description, and on the other receive nothing whatever for the business built up, should it happen to prove a success and the local authority take a fancy to it. That this is so, no one who has studied the subject can doubt. The inference seems, therefore, to be irresistible. Either the advocates of municipal electric lighting do not trouble to read the Acts relating to it or, suspecting lack of enthusiasm on the part of the ratepayer, they try to frighten him with the bogey aforesaid. Much can be said for and against municipal electric lighting, but neither the argument for nor the argument against will suffer from being based on fact.

THE disinterested philanthropist who is going about the country selling "electric" spectacles at a guinea a pair is obviously a raw hand. "*L'audace, encore de l'audace, toujours de l'audace*" is an excellent maxim for quacks, but when desirous of securing complete immunity from newspaper comment and criticism they have need of another. Had this vendor of "electric" spectacles, warranted to simultaneously cure sore eyes and rheumatism, taken care to "advertise cleverly, advertise lavishly, and advertise always," the letters which have been allowed to appear in the daily Press denouncing his malpractices, and the editorial utterances that have supplemented these letters, would, the dull season notwithstanding, have been irrevocably committed to the bourn whence no copy returns—the editorial waste-paper basket.

Inter-Urban Telephony.—The telephone traffic between Paris and Havre has increased so much that a third circuit has been rendered necessary.

Cable Interruptions:

	Dates of Interruptions.
Aden-Zanzibar	August 9th.
Falmouth-Bilbao	„ 17th.

Harrogate.—At a meeting of the Town Council on Monday it was decided by thirteen votes to seven to undertake the electric lighting of the town.

Halifax.—A Local Government Board Inquiry was held last week relative to the proposed Corporation electric lighting loan of £30,000. The scheme was opposed by the Halifax Mutual Electric Light and Power Company.

Bolton.—Major-Gen. Crozier, one of the inspectors of the Local Government Board, conducted an inquiry at Bolton on Tuesday into the application of the Corporation to secure power to borrow £40,000 for electric lighting works.

A New Chair of Applied Electricity.—It is announced by the French Minister of Public Works that a Chair of Applied Electricity has been instituted at l'École Nationale des Ponts et Chaussées, the Parisian college of civil engineering.

Manchester.—At a meeting of the Town Council last week the report of the Highways Committee with regard to the question of underground telephone wires, which was summarised on page 357 of our issue of August 4th, came up for adoption. An amendment to the effect that more time be allowed to consider the question was carried.

Copper.—During the past fortnight deliveries in England and France exceeded supplies by nearly 1,000 tons, and the total visible supply now amounts to only 49,557 tons, compared with 50,483 tons on July 31st. The price of copper, however, continues to fall, and Chili bars are now quoted at £41. 2s. 6d. a ton, or 10s. a ton lower than a fortnight ago.

The City Polytechnic.—Courses of evening lectures and practical instruction in mechanical engineering, machine design and drawing, by Mr. Henry Adams, will be commenced at the City Polytechnic, City of London College, early in October. There will also be courses of instruction in electricity, mechanics, mathematics, and other sciences relating to electrical engineering.

Engineering Education.—One of the divisions of the Engineering Congress, which held its meeting at the Chicago Exhibition from July 21st to August 4th, was that of Engineering Education. Twenty-two Papers were read, a number of which had more or less bearing on the education of electrical engineers. A permanent organisation has been effected under the name of the "Society for the Promotion of Engineering Education."

The Hermite Sewage Process.—Advantage is going to be taken of the forthcoming Hygienic Exhibition at Havre to carry out on a large scale the Hermite electric disinfection process. M. Hermite's process, which was described in *The Electrician* at the time of its inception, consists simply in the electrolysis of sea water, the electrolysed liquid being used to flush the sewers. During the Exhibition a section of the Havre sewers will be treated in this way.

Arc Light Accident at Leeds.—An inquest was held this week at Leeds on George Sykes, 21, an electrical engineer employed on the Midland Railway, who died at the Infirmary from a fall caused by an electric shock. He was attending to a lamp in the goods yard, and put his hand inside. A flash occurred, causing him to fall from a ladder, fracturing his skull and spine. He had neglected to put on indiarubber gloves. Verdict of accidental death was returned.

The International Electrical Congress.—Our New York correspondent, writing under date of August 11th, states that all the foreign delegates to the International Electrical Congress, at Chicago, had either arrived or were on their way. The complete list is as follows:—United States, Rowland, Carhart, Mendenhall, Nichols, and Elihu Thomson; England, Ayrton, Preece, Cardew, Siemens, and S. P. Thompson; Germany, Helmholtz, Schraeder, Voit, Lummer, and Budde; France, Mascart, Hospitalier, De la Touanne, and Violle; Italy, Ferraris.

The City Lighting.—We trust that those responsible will take warning:—If the statement be true that the City Commissioners of Sewers contemplate removing the street gas lamps on an early date, it is, thinks the *Gas World*, an intention that says little for their wisdom. "It is not many weeks since we had occasion to report an extensive failure of the arc lamps that are supposed to be a perfect substitute for the gas lamps. To even talk about removing the gas lamps while experience shows that the probability of such failures has to be reckoned with is folly, and to remove them would be almost sheer madness."

Alternative Telegraph Lines.—The advantages of alternative lines of telegraph, says the *Indian Engineer*, have been strikingly illustrated during the present monsoon season. The direct line from Calcutta to Assam has been broken, owing to floods between Jalpaiguri and Dhubri, two rivers at least having changed their course and washed away the masts from which the wires are suspended at the crossings. Messages have consequently had to be sent by another route pending repairs, and the only one available is by way of Burma. It is a long distance round through Mandalay and Tammu, but the work has been satisfactorily disposed of, the Telegraph Department, as usual, being readily equal to emergencies.

Transmission of Power in Switzerland.—An important scheme for the transmission of power is now being considered in Switzerland. It is proposed, says *Engineering*, to dam the River Reuse and convey the water to a storage and distributing reservoir having a capacity of 3,000,000 cubic feet, and situated at Combe Garrot. From here the water is to be distributed to the communities of Neuchâtel, Loche, and La Chaux-de-Fonds. The head available will be about 300ft., and the conduits will have a capacity of 177 cubic feet per second, though the flow of the river varies between 100 and 60 cubic feet per second only. The power will be distributed from the turbine stations by electricity, the distances being from 7½ to 11 miles.

Wind Power.—Some years ago an attempt was made under the auspices of the Duc de Feltre and M. L. Vigreux to drive the dynamos at the Pointe de la Hève Lighthouse by wind-power. The wind, however, as is its custom, blew when and where it listed, and ended one fine, or rather one stormy, day by overthrowing the ungainly apparatus installed on the exposed headland. M. Max de Nansouty, in alluding to this attempt to "harness" the wind, suggests that next time a similar attempt is made it would be as well to try the effect of surrounding the "atmospheric turbines" by strong towers, and directing the wind on to the vanes by nozzles in much the same way as the water is directed on to the buckets of a Pelton wheel. This idea of "canalising" air currents is, it is said, actually engaging the attention of windmill experts.

Electric Launches.—Much, very much, says the *Engineer*, is said in the Press occasionally about the advantages of electricity as the motive power for launches, &c. Enthusiastic persons talk and write about an electric torpedo boat. There is something which appeals very strongly to the imagination in the idea of a boat urged along at a high speed, making no noise, emitting neither sparks, nor smoke, nor smell, to indicate its whereabouts. That a torpedo boat which would do this would be an acquisition to any navy, now goes without saying. As a means of converting electrical energy into mechanical work an electric motor is practically a perfect machine. Could we stow the electrical energy in receptacles one-tenth the size and weight of the present storage cells, and did the operation take about one-tenth of the time now occupied, there would be no need to discuss the most suitable motor. The difficulty is with the cells.

Telephone and Telegraph Wires at Brighton.—At the meeting of the Brighton Council last week, on the Works Committee report coming up for adoption, Councillor Sutton, referring to the decision of the Committee to comply with an application of the Postal Telegraph authorities for permission to open the roadway in North-street for the purpose of underground telegraph wires, asked whether this excavation could not be made final so that the inhabitants of North-street might have a little rest from such nuisances. Councillor E. A. Dell thought the Corporation should compel the telegraph authorities to lay their wires at night time or refuse to allow the work to be carried out at all. On the draft of bye-laws with respect to telephone and telegraph wires over public streets being brought forward for confirmation, Councillor E. A. Dell asked whether he had any legal power to cut the telephone wires that ran over his premises, if he thought fit, and was answered in the affirmative.

Electric Lighting and Fire Risks.—Statistics of the conflagrations in the United States during the last year have recently been analysed by M. Boudinet, who has shown that out of the 17,095 fires in 60 large towns only 203 have been caused by electricity, and that out of the total damage of $22,781,532 which has resulted from these fires only $281,241 have been lost on account of injury wrought by electric currents. It must be remembered that in the United States electricity is far more used for general purposes than in this country, and that careful work is not so common there as it is here. Thus, with a widespread use of this mode of lighting and transmitting power, not more than 1·19 per cent. of the fires and only 1·23 per cent. of the damage can be attributed to its use. Of the 203 fires due to electrical causes 59 occurred in New York, 26 in Boston, 16 in Cleveland, 12 in Lowell, 11 in Minneapolis, and 10 in Philadelphia.

Terrestrial Magnetism.—An interesting note on the variation of the earth's magnetism in the neighbourhood of a hill containing magnetic rocks, by MM. Oddone and Franchi, has, says *Nature*, appeared in the "Annali dell' Ufficio Centrale di Meteorologia e Geodinamica" (Vol. XII., part I.). The hill was composed of serpentine, and had, roughly speaking, a lenticular shape, being 1,500m. long, and 500m. broad, with its greatest length north-west and south-east. The declination is the only element up to now observed. As an example of the magnitude of the deviations obtained we may give the following set of readings (corrected for diurnal variation), along a line running north-east from the hill. At the out-crop of the serpentine the reading for the needle was 11deg. 20min.; about 100m. away, 10deg. 35min.; about 500m. away, 9deg. 56min. 30sec.; while at a distance of 700m. it was 9deg. 50min. 30sec. In every case an attraction of the north pointing pole of the needle towards the serpentine was obtained, thus indicating that the mass of rock was magnetised with its upper end a south pole.

Alternating Currents of High Pressure.—At a recent meeting of the Société Française de Physique a communication was made by M. Leduc on the production of high-pressure alternating currents by means of electrostatic influence machines. Experiments were carried out with the aid of a 2-plate Wimshurst machine. The alternating currents obtained in this way possess properties analagous to, but not identical with, those upon which Tesla has been making researches. Conductors traversed by these currents became luminous, and, by varying the shape of the conductors, or by approaching them with other conductors, a variety of beautiful luminous effects are produced. The best arrangement is that in which one of the external armatures is connected to earth, the other being connected by means of a chain to the table of the machine. When this chain is enveloped in a length of caoutchouc tube and held in the hand, a phosphorescent light is produced between the tube and the hand. These currents when passed through the human body are found to act on the motor and sensory nerves, while Teslaic currents do not.

The "Tromometer."—Electricity has either in imagination or in fact been pressed into many strange services, but we doubt whether it has performed anything more curious than it does in the case of the "tromometer," which is an instrument devised by a M. Quintard, of Angers, to determine the degree of shakiness or steadiness of the human hand. The "tromometer" consists of a knitting needle and a sheet of metal pierced with a series of gradually diminishing holes. One pole of a battery is connected to the knitting needle, the other to the draw plate, an electric bell being also in circuit. The "subject" has then to insert the needle through the holes in succession, beginning at the largest, until the amplitude of his "shakes"

Digitized by Google

is such that he ends by touching the sides of the hole, a result which is announced to the world at large by the ringing of the electric bell. It is suggested that a "tromometer" would be a useful adjunct to the equipment of a competing rifleman; unfortunately for this idea, steadiness of hand and accurate shooting do not by any means go together, so that the indications of a "tromometer" would, as likely as not, be a cause of unnecessary discouragement.

Electric Lighthouses.—At the recent session of the International Maritime Congress several Papers of interest to electrical engineers were read. Among these we may notice a Paper by Mr. Stevenson on lighthouses, which describes the works which have lately been carried out for improving the lights on our coasts. In the discussion which ensued, the relative merits of gas, oil, and electricity, for illuminating purposes were considered. It has long been supposed that the last-named mode of lighting, while superior to the others in clear weather, is incapable of producing penetrating rays when the weather is foggy. The results of experiments which have been carried out by the Lighthouse Commission would tend, however, to show that this opinion is mistaken; and that electricity, on account of the direct penetrating power of the light as well as because of its more complete reflection from the clouds, is the most satisfactory means of lighting for coast lighthouses. Mr. Wigham, who took part in the discussion, considers it of such great importance that this point should be carefully determined, that he has offered to the Irish Lighthouse authorities to carry out at his own expense a series of experiments on lights to be fixed in Dublin Bay.

The Post Office and the National Telephone Company.—At a meeting of the Telephone Committee of the Glasgow Town Council on Tuesday the proposed agreement between the Postmaster-General and the National Telephone Company, by which it is thought the streets of the City would practically be handed over to the Company, was under consideration. It was agreed, in order to strengthen the hands of the City Members of Parliament in preventing the agreement being completed, to send two members of the Telephone Committee to London to have an interview with the Postmaster-General. We understand, says the *Glasgow Herald*, that the Association of Municipalities is moving in the direction of supporting Glasgow and other corporations in insisting that the Postmaster-General should make known the terms of agreement with the Telephone Company before signing it; also to oppose the Company getting any powers beyond what they at present possess. An engineer, it is further stated, has written to a member of the Telephone Committee to the effect that there is reason to believe that the National Telephone Company have so negotiated the agreement that it will be found that corporations will be placed at a vast disadvantage, and that the agreement will virtually confer on the National Company a monopoly of telephone exchange work in the country. The agreement must, he says, in the public interest, be laid before Parliament *unsigned*.

Pioneer Inventors.—Much space, more or less valuable, says the *Electrical World* of new York, has been, and probably will continue to be, devoted to accounts of "pioneer inventors"—accounts which are usually couched in highly eulogistic terms, sometimes even approaching the hysterical in expression. We use the expression "pioneer inventors" in its paradoxical sense as applied to those who first pointed out or made use of an obvious application that involved no exercise whatever of the inventive faculty. To particularise, we will suppose that once upon a time a man saw a small electric motor, then very rare, in operation, and noticed that its shaft revolved; he is also aware of the fact that other shafts revolve, and it occurs to him that by hitching a motor to one of these other shafts it will be revolved by the motor. Acting on the thought, he makes a model, perhaps astonishes some of his neighbours, and that is the last of it as far as he is concerned. Many years later, when motors have assumed a commercial form, and are generally employed, the model is brought to light, a journalistic writer gets up an article with many illustrations, including, perhaps, a portrait, a view of the man's former residence and of his grave; the world's ingratitude to its great inventors is enlarged upon, or a quotation from Gray's "Elegy" neatly worked in, and another name is added to the list of pioneer inventors. Most of the accounts of pioneer inventors would be merely amusing were it it not for the fact that the claims made are eagerly accepted by writers of popular books on account of the supposed interest they will give their narrative, with the consequence that the credit of the real inventor is diminished, or perhaps entirely lost sight of.

Electric Search-Light Applied to Pit Sinking.—In a Paper recently read before the Mining Institute of Scotland, Mr. James Baird described an electric search-light, which has been applied to pit sinking near Paisley. The apparatus, which is suspended over the pit's mouth, consists of an arc lamp, a lens, and a mirror, the whole being enclosed in a sheet iron case, 4ft. 9in. by 1ft. 8in., by 1ft. 8in. Access to the lamp is obtained by a sliding shutter on each side of the case. The light is focussed or adjusted by a screw on the top of the outside of the case, and when occasion requires the lamp can be adjusted to diffuse light throughout the whole shaft, or be concentrated at the bottom, where the men are working. The mirror is hung on its centre, and can be moved in a vertical direction, so as to deflect the rays of light to where they are wanted, after which it is held in position by a thumb-screw. The shaft at Walkinshaw is circular, 13ft. in diameter and 43 fathoms deep. It is lined with brick all the way. From Mr. Baird's experience he found that the following advantages were obtained with the lamp:—(1st.) The light at the shaft bottom was far in excess of that got from the ordinary sinker's lamps, consequently more work could be performed in a given time. (2nd.) The lamp being stationed on the surface could be got at easily at any time for adjustment without inconvenience to the sinkers; and in the event of the strata giving off fire-damp, it would give perfect immunity from danger of explosion. (3rd.) By the aid of the light those in charge could see from the surface what was going on below, and this is not altogether an unimportant matter; in fact, a practical gentleman visiting the colliery was delighted with this aspect of the light, and said that it was worth all the outlay, even if it served no other purpose than this.

Whitworth Scholarships.—The following candidates have been successful in the competition for the Whitworth scholarships and exhibitions, 1893:—

Name.	Age.	Occupation.	Address.	Value of scholarships and exhibitions awarded.
(1) Scholarships (tenable for 3 years)				
Hamilton, William ..	23	Electrical engineer	Glasgow ..	£125 a year each
Longbottom, J. G...	23	Engineer	Keighley ...	
Malpas, Arthur E....	22	Engineer	London	
Durley, Richard J..	25	Engineer	London	
(2) Exhibitions (tenable for 1 year)				£
Smith, Charles F. ..	20	Mechanical engineer ..	Glasgow ..	50
Ball, John	21	Student.....	Derby	50
Buchan, William ...	21	Engineer	Glasgow ...	50
Chambers, John B..	19	Engineer's apprentice	London	50
Loveridge, Henry J.	21	Engine fitter	Southsea ...	50
Ireland, William F...	25	Draughtsman	Glasgow ...	50
Fearnley, George W.	21	Student.....	Shipley	50
Styles, Oliver	23	Engineer student.. ...	Edinburgh ..	50
Russell, George M. ..	21	Shipwright apprentice	Portsmouth.	50
Jude, Alexander A...	17	Engineer's apprentice.	Hull	50
Amor, Edward R. ...	17	Engine fitter „	Devonport ..	50
Jeffrey, Joseph... ...	25	Engineer's student ...	Birmingham	50
Reynolds, Paul J. ...	19	Fitter	Plumstead...	50
Pilkington, Thomas..	25	Fitter	London	50
Reynolds, Richard..	24	Fitter	Cardiff	50
Wilson, George	21	Mechanical engineer..	Sheffield ...	50
Hammant, W. O. ...	20	Fitter	Plumstead ..	50
Orr, John	23	Engineer's apprentice.	Airdrie	50
Chubb, I. William...	22	Draughtsman	London	50
Smith, Henry.....	21	Engineer's apprentice	Brighton ...	50
Green, Frederick D.	21	Engineer's apprentice	Wanstead E.	50
Powell, John	21	Fitter	Crewe	50
Hardy, James H. ...	24	Mechanic	Woodley ..	50
Shepherd, James H.	23	Draughtsman	Swindon ..	50
Thompson, Herbert..	23	Engineer	Sheffield ..	50
Stephens, Evan	23	Draughtsman	Swindon ...	50
Morrall, Henry E. ...	20	Draughtsman	Wolverton ..	50
Bates, Herbert	18	Fitter	Manchester..	50
Hill, Charles H.....	20	Engineer's apprentice	Stratford E.	50

ELECTROMAGNETIC THEORY.—LIII.

BY OLIVER HEAVISIDE.

(Continued from page 257.)

§ 208. The detailed application of the principles already discussed to the data which occur in practice, or which may occur in later practice, would lead us into technical complications which would be out of place in the present stage of development of this work. Only a few general considerations can be taken up here in connection with the theory of plane waves. We have seen that there are four distinct quantities which fundamentally control the propagation of "signals" or disturbances along a circuit, symbolised by R, K, L, and S, the resistance, external conductance, inductance, and permittance; whilst there are two distinct variables, the transverse voltage V and the circuital gaussage C, or the difference of potential (in an extended sense) of the leads in a reference plane, and the current in the leads. The words voltage and gaussage were proposed in § 27 to represent electromotive force and magnetomotive force, and have been employed experimentally to see how they would work. They work very well for theoretical purposes, but I observe that they are not generally or universally approved of, perhaps on account of the termination "age," or because of the commencements volt and gauss being unitary names. It is open, of course, to anyone to find names which shall be more suitable or meet with general approval.

But I stick to inductance. Of all the words which I have proposed, that one seems to me to be, more than any other except impedance and conductance, the right word in the right place, and I am bound to think it possible that some of those who prefer the old "coefficient of self-induction," do not fully appreciate the vital significance of inductance in a theory of intermediate action of a medium. The idea of the direct mutual action of current-elements upon one another is played out. And as regards the name of the practical unit of inductance, I think the best name is mac, in honour of the man who knew something about self-induction, of course. Many other names have been proposed, but none so good as mac. Some critic has made etymological objections. But what has etymology got to do with it? The proper place for etymology is the grammar book. I always hated grammar. The teaching of grammar to children is a barbarous practice, and should be abolished. They should be taught to speak correctly by example, not by unutterably dull and stupid and inefficient rules. The science of grammar should come last, as a study for learned men who are inclined to verbal finnicking. Our savage forefathers knew no grammar. But they made far better words than the learned grammarians. Nothing is more admirable than the simplicity of the old style of short words, as in the "A sad lad," "A bad dog," of the spelling book. If you transform these to "A lugubrious juvenile," "A vicious canine," where is the improvement?

Now, as we have already explained the characteristics of distortion of plane waves by conductance in the medium generally, of two kinds, acting differently on the electric and magnetic fluxes, the corresponding relations in a long circuit of leads need be only briefly mentioned. Consider an infinitely long circuit of parallel and equal resisting leads under uniform external conditions, and governable by the relations laid down. Let it be, at a given moment, wholly free from charge or current except at one place, where there is merely a charge, say Q_0. Or, say $Q_0 = SV_0$ on unit length only at the place. Left to itself, this will spread. But it will do so in widely diverse manners under different circumstances, although there are some common characteristics. The speed of propagation of disturbances is $v = (LS)^{-\frac{1}{2}}$, independent of the values of R and K, the dissipation constants. Thus, at time t after the spreading begins, we are bound to find the charge, or what is left of it, within the region of length $2vt$, being vt on each side of the origin. Beyond this region there is no disturbance.

Next as regards the amount of the charge. It cannot increase, but it may diminish. If the insulation be perfect, which means that K = 0, the charge remains constant. It is unaffected by the resistance of the leads, although energy is wasted in them. It only decreases by the external conductance, or by equivalent leakage. Then we have

$$Q = Q_0 \epsilon^{-Kt/S}, \quad \ldots\ldots (1).$$

to express the charge Q at time t, decreasing according to the well-known exponential law.

As regards the manner of spreading, either with or without the subsidence, this is represented in the exact theory by the spreading and subsidence of displacement in a medium which is magnetically as well as electrically conductive, although the former property does not affect the total amount of displacement. We see, therefore, that the distortionless case, which occurs when the time constants L/R and S/K are equal, forms a natural division between two distinct kinds of resultant distortion. In this neutral case, the charge Q_0 splits into two halves which at once separate from one another at relative speed $2v$. At time t later they are each attenuated to

$$\tfrac{1}{2}Q = \tfrac{1}{2}Q_0 \epsilon^{-Kt/S}. \quad \ldots\ldots (2).$$

The energy was wholly electric to begin with, but in each of the resulting waves it is half electric and half magnetic, because they are pure waves. As they attenuate, their energy is wasted, and this occurs so that half is wasted by the resistance of the leads, and half by reason of the external conductance. This is necessary in order that a pure wave shall remain pure. The final result is attenuation of the two charges to zero, when they are infinitely widely separated, and with this a complete simultaneous disappearance of the other characteristics, as the magnetic force. In the exceptional case of no resistance and no leakage, there is, of course, an everlasting persistence of the two charges and of the waves of which they form a feature. They go out of range, but not out of existence. In all other cases but the distortionless one, the charge (or the remains of the original charge) is only partly in the plane waves at the two ends of the disturbed region, the rest being diffused between them. But this may happen in two ways. The total charge at time t is expressed by (1) above. But the charge in the terminal waves, half in each, is given by

$$Q_0 \cdot \epsilon^{-(R/2L + K/2S)t}, \quad \ldots\ldots (3)$$

reducing to (2) doubled in the distortionless case. Therefore the excess of (1) over (3) is the amount of the diffused charge. It is

$$Q_0 \cdot \epsilon^{-Kt/S}(1 - \epsilon^{-(R/2L - K/2S)t}), \quad \ldots (4)$$

and is positive or negative according as R/L is greater or less than K/S.

That is, when the resistance of the leads is in excess, the charge is positive between the waves as well as in them. But when the leakage is in excess the intermediate charge is negative. This happens equivalently when the inductance is in excess, or the permittance in deficit. How this reversal comes about has been already explained in the exact theory. In the present circumstances we may say that an intermediate resistance in the circuit of the leads reflects V positively and C negatively, whilst an intermediate leak reflects C positively and V negatively. The same applies to the elements of the circuit, and from this follows the reversal of V when leakage is in excess. Whether the tailing be of the usual positive or of the negative kind (referred to the charge), the maximum or minimum density is in the middle; that is, at the origin. The density decreases symmetrically both ways to the two ends, where the plane waves are to be found. When they have attenuated to practically nothing, there is left merely the widely diffused charge, unless it has attenuated similarly. With the resistance largely in excess, there may be nearly all the charge left when the terminal waves have become of insensible significance. But if the leakage be in excess, the disappearance of the terminal waves is accompanied by a similar disappearance of the intermediate negative charge, because the total charge is always positive.

So far regarding the spreading of a charge, next consider the spreading of induction. The magnetic analogue of Q is P = LC, the magnetic momentum per unit length of circuit. So, as L is constant, the spreading of P is represented by that of C. Suppose initially there be current C_0 in unit length at the

Digitized by Google

origin, with momentum $P_0 = LC_0$, and no charge there or elsewhere. This also splits immediately into two plane waves, which only differ from those arising from a charge in having similar C's and opposite V's instead of similar V's and opposite C's.

The total induction remains constant only if the leads have no resistance. In general it decreases, so that at time t we have

$$P = P_0 \cdot \epsilon^{-Rt/L} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

At the same time the amount in the terminal waves, half in each, is

$$P_0 \cdot \epsilon^{-(R/2L + K/2S)t} \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The amount between the terminal waves is, therefore, the excess of (5) over (6), which is

$$P_0 \epsilon^{-Rt/L} \left(1 - \epsilon^{-(K/2S - R/2L)t}\right) \quad . \quad . \quad . \quad (7)$$

These equations (5), (6), (7), may be instructively compared with the set (1), (3), (4), their analogues. Notice that in transforming from one set to the other, we exchange V and C, Q and P, R and K, L and S. In the exact theory the R in these formulæ would also be a conductance, as before described.

By (7) we see that in the distortionless case all the induction left is in the terminal waves, which is to be expected. But we require the leakage to be in excess for the intermediate induction to be positive, and conversely the resistance must be in excess for it to be negative. Of course, the initial induction is assumed to be positive. Also observe that leakage by itself has no effect on the total induction except to redistribute it, just as the resistance of the leads has no attenuating effect on the total charge. As before, the maximum or minimum density of induction is at the origin, though, of course, the terminal inductions may have greater or smaller density than this, according to the extent of attenuation at the moment concerned. Remember that the destruction of induction by the resistance of the leads is represented, in the exact theory, by its destruction by the equivalent magnetic conductance externally.

Putting together the preceding results, we may readily see the effect of having both V and C initially at any spot. One case is specially noteworthy. Take $V_0 = Lv C_0$ initially. This means a pure plane wave sheet, travelling in the positive direction. There is, therefore, no initial splitting, and the wave just goes on. To what extent this will continue depends upon the relation the constants of the circuit bear to the distortionless state. When the latter obtains, the wave is transmitted without spreading out behind, so that at time t the initial state, if existent over unit length, will be found over unit length at distance vt to the right, attenuated to

$$V = LvC = V_0 \epsilon^{-Rt/L}, \quad . \quad . \quad . \quad . \quad (8),$$

where for t may be substituted its equivalent x/v. In all other cases there is reflection in transit, and the reflected portions travel back, besides getting mixed together, thus making a tail of length $2vt$, half on each side of the origin, but now, of course, without a head at the negative end to balance the one at the positive end.

If the resistance be in excess, the charge in the tail is positive and the current is negative, at least initially; whilst if the leakage be in excess, the current is positive and the charge initially negative. *See* §§ 195 to 199 for more details, which may be readily translated to suit the present case. The total charge subsides according to equation (1) above, and the total induction according to (5). Similarly (3) represents the charge in the one terminal wave (instead of both, as there), and (6) shows the induction in the terminal wave.

If initially $V_0 = -LvC_0$, this means a negative wave (going to the left) to start with. This needs no separate notice in detail.

§ 209. The distortionless state forms a simple and natural boundary between two diverse kinds of propagation of a complicated nature, in each of which there is continuous distortion which is ultimately unlimited. Given time enough, and a circuit of infinite length to work with, the least departure from the distortionless condition would be sufficient to allow all the natural changes to be gone through, with ultimate unlimited distortion. The attenuation is a separate matter in this connection, though itself of great importance. If, however, we are only concerned with the distortion produced in a finite interval of time, which may be quite small, then the matter may be differently regarded. There is much or little distortion, generally speaking, according as the ratios R L and K/S are nearly equal or widely different. But this needs to be understood with caution, for obviously there may be next to no distortion of signals even when the distortionless state is widely departed from, provided the changes of charge and current are made slowly enough. But when this is not the case, and there is marked distortion of waves in transit, then we shall increase it by making the time-constants more unequal than they are, and decrease it by a tendency to equalisation. Furthermore, this process is a continuous one, so that, starting from the distortionless state connected with equal time-constants, we may, by continuously increasing one time-constant, bring on continuously increasing distortion of one kind, or else, by increasing the other, whilst the first is kept constant, bring on continuously increasing distortion of the other kind. And this is true by variation of any one of the four quantities concerned, the resistance, leakage, inductance, and permittance, to prove which we need only remark that with any values given to these constants we can equalise the time-constants and abolish the distortion altogether by altering any one only of the four.

When a circuit has been brought to this state, then arbitrary signals of any size and manner of variation, originated at the beginning of the circuit, will run along it at the speed of light, and in doing so suffer no alteration save a weakening according to the exponential law given above. The voltage and gaussage at any spot will be always in the same phase, and the succession of values will faithfully repeat those at the origin. If the circuit be infinitely long, the train of disturbances will run out to infinity, of course, though it may be still a long way from infinity when the attenuation is so great as to make the disturbances insensible. Therefore, disregarding the attenuation, there is no limiting distance of possible signalling. More than that, it is not only possible, but perfect signalling, according to this theory.

But there is no perfection in this world. Even if a circuit were constructed with constant R, K, L, and S, and with R/L = K/S exactly, so that it should be truly distortionless in this practical theory, it would not be so in reality. There are several disturbing causes, which, though they might not be of much importance in general, would serve to prevent the attainment of the clean-cut perfection of the theory which ignores them. Instead of zero distortion, then, it is practically only a state of minimum distortion that is attainable. But it may be a very good imitation of the theoretical ideal. It is unnecessary to enlarge upon the necessary failure of a professedly approximate theory when pushed to extremes. It is sufficient to say that the ignored disturbing influences alone would serve to set a practical limit, even if the condition R/L = K/S were truly attained, and attenuation were of no importance.

But there is an influence in full action in the practical theory itself which must not be overlooked, namely, the attenuation due to resistance and leakage. Of what use would it be to have a distortionless circuit if it took nearly all the life out of the current in the first 100 miles, when you want it to go 1,000? Now, on paper nothing is easier than to increase the battery power to any extent you want, till, in fact, the minute fraction which got to the desired distance became magnified up to a recognisable size. But practically there would usually be strong reasons against this process. At any rate, it is impossible to overlook the attenuation. It is not merely enough that signals should arrive without being distorted too much, but they must also be big enough to be useful. If an Atlantic cable of the present type were made distortionless by the addition of leakage, there would be no sign of any signals at the distant end with any reasonable battery power. Nor can we say that telephony is possible on a circuit of given type to this or that distance merely because a certain calculable and small amount of distortion occurs at that distance. Nor can we fix any limiting distance by consideration of distortion alone. And even if we could magnify very weak currents, say

Digitized by Google

a thousandfold, at the receiving end, we should simultaneously magnify the foreign interferences. In a normal state of things interferences should be only a small fraction of the principal or working current. But if the latter be too much attenuated, the interferences become relatively important, and a source of very serious distortion. We are, therefore, led to examine the influence of the different circuit constants on the attenuation, as compared with their influence on the distortion.

(To be continued.)

OCEAN TELEPHONY.*

BY SILVANUS P. THOMPSON, D.SC., F.R.S.

I.—Introductory.

It is contrary to the scientific spirit of progress to admit that any art or application of science can stand still, or that any of its developments are final. To bridge the ocean by an electric telegraph was a mighty achievement. To speak through a wire the audible syllables of language was a marvel. To accelerate telegraphic transmission by automatic devices until a speed of even 500 words per minute was attained was a bewildering accomplishment. But with the attainment of these three tremendous strides, finality has not been reached. The ocean cable of to-day is practically unchanged from what it was thirty years ago. It speaks only with the still slow signals of the mirror galvanometer, or of the siphon recorder. Six or eight words per minute slowly spelled out are the usual limits of working of an Atlantic cable. The spoken telephonic word, and the rapid automatic telegraphic message are too nimble for it. For such rapid signalling it is dumb. That a submarine cable clad in its coating of gutta-percha would retard the rate of signalling was predicted by Faraday, and verified when the first long cable was laid. Many have been the subsequent devices to increase the speed of signalling by the use of condensers and the like. They have all been devices to be applied either at the transmitting, or at the sending end, or at both. Arrangements of condensers and resistances so combined as to act as an artificial cable, imitating the retardations of an actual cable, have been found indispensable adjuncts for balancing the properties of the cable in order to adapt it for duplex working. Varley proposed, many years ago, another device, namely, to introduce at each end an inductive shunt; that is to say, to apply as a shunt a wire possessing both resistance and self-induction. But in spite of the use of condensers, of artificial cables, and of inductive shunts, the retardation of the long submarine cable has proved hitherto insuperable save for slow signals. In the sending of each signal the gutta-percha coating becomes charged, and this charge must be, as it were, swept out before the next signal can be sent. Retardation triumphs over the telephone and the automatic rapid telegraph.

And yet no reasonable electrician can doubt for a moment that ocean telephony must come, or that the resources of science are equal to the solution of the problem. It is because the author thinks that he has found the way to the solution that he ventures to place on record the ideas which have been growing in his mind for three years past, together with some of the evidence by which their soundness may be tested.

If the solution at which he has arrived seems strange to the ordinary telegraph electrician or cable engineer, it is because that solution has dawned upon him out of a different domain of science, namely from the study of alternate-current phenomena. If the solution he now propounds seems impracticable to cable engineers accustomed to the old type of cable that has persisted now for 30 years, he would reply that it is the business of the engineer to make it practicable. If the business of the world demands a new type of cable then the engineer must be found who can manufacture and lay it. Seeing that such a cable, once laid, will (if the author's views are correct) perform the work at a rate that would at present require, say, 10 ordinary cables to perform, there is a very powerful inducement to the engineer to find a practicable way of realising that which theory indicates as the submarine cable of the future.

* Paper read before the International Electrical Congress at Chicago, August 22nd.

II.—Devices to Neutralise the Retarding Effects of Capacity in Submarine Cables.

The retardation of signalling, which is found in submarine cables, is due to the capacity of the cable, and this capacity is distributed fairly uniformly along the cable. Owing to this circumstance, all attempts made hitherto to annul or compensate its operation by means of devices situated at the *ends* of the cable, have met with very limited success. Whereas, the ordinary speed of signalling through an Atlantic cable is about eight words or so per minute, it would be quite possible to send 400 words per minute through a line of the same resistance, but destitute of capacity.

The only effective way to annul the retarding effects of a *distributed* capacity is to apply a *distributed* remedy; that is to say, abandoning the idea of compensating it by devices placed at the ends of the cable, means must be sought for applying compensating devices *distributively* along the length of the cable, either at intervals or continuously.

It is well known that the effects of electromagnetic induction are, in a sense, reciprocal to those of capacity. The most familiar modern example is that of the opposite operation of self-induction and of capacity on the phase of an alternate current, the one tending to produce a lag, the other a lead, in the phase of the current relatively to the electromotive force. It is obvious that if electrostatic capacity can be used to correct the effects of electromagnetic induction, conversely it will be possible to use electromagnetic induction to correct the retarding effects of electrostatic capacity.

There are two main modes of action of electromagnetic induction, namely, *mutual induction*, from wire to wire (with or without an iron core intervening, and sometimes called electrodynamic induction), and *self-induction* when the current in a wire reacts inductively on itself. Both are known to be due to the setting-up, by currents, of magnetic fields in their neighbourhood.

There are a very large number of ways in which, theoretically, the end may be obtained of compensating the effect of the distributed capacity by means of distributive electromagnetic induction. It will suffice here to consider two simple cases, and for the sake of simplicity it will be supposed

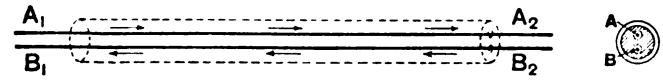

Fig. 1.

that each is applied to the case of a cable containing two insulated wires for the out-going and returning currents. Such a cable may be represented in Fig. 1, where A A is the out-going wire or "line," and B B the incoming wire or return. In the subsequent figures the sheathing will not be specifically indicated.

Case I.—*Use of Self-Induction Devices Distributively.*

In this case a series of self-induction coils of sufficiently high resistance and sufficiently great inductivity are placed across at intervals from the A conductor to the B conductor. In order the better to follow the action it will be convenient

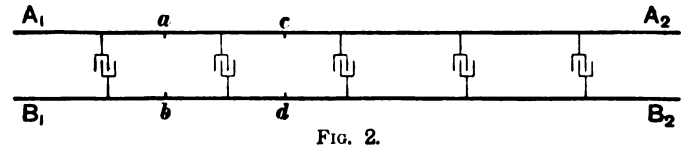

Fig. 2.

to represent the distributed capacity as in Fig. 2. Here the two conductors $A_1 A_2$, $B_1 B_2$, are drawn as though each in itself was devoid of capacity, but that a capacity was given to them in a distributive way by arranging a number of condensers along at intervals, each condenser having one coating joined to the A line, and the other coating joined to the B line.

Digitized by Google

Suppose the signalling to take place from the left-hand end, and that a wave of current is being thrown into the circuit at A_1 by a transmitting apparatus joined to $A_1 B_1$. Were there no capacity or inductivity in the line $A_1 A_2$, the wave would travel simply along without retardation. But the presence of capacity changes all this. When the potential at A_1 is rising the potential at some point along the line a would not rise simultaneously, because of the capacity in the intervening part of the conductor. The potential at a cannot rise to its proper value until the condenser between A_1 and a has received its charge. Similarly, the potential at c does not rise as soon as at a, because of the action of the capacity between c and a. Again, when the potential at A_1 is falling, it will not also fall at a or at c simultaneously, because the condensers in between tend to keep up the potential, and take time to empty themselves. Whenever the potential at any part of the line is rising, some of the current tends to flow into the condenser at that part, with the result that the rise of potential in that part is delayed, while the current beyond that part is for the moment smaller than the current that is coming up to the part. Further, when the potential at any part is falling

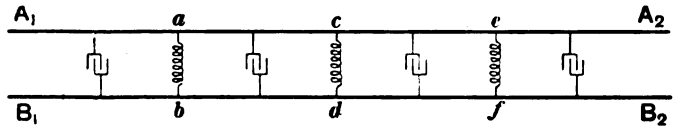

Fig. 3.

there is a tendency for current to flow out of the condenser at that part, and thereby keep up the potential a little later; so that at that moment the current flowing away from the part in question is greater than that flowing towards the part. If nothing is done to compensate this action, the effect would be that virtually all the wave thrown into the cable at A_1 would be taken up in playing into and out of the successive condensers, and so only an insignificant and much-retarded fraction of it would reach the end A_2.

Now suppose that self-induction coils are placed across the cable at the proper intervals, as in Fig. 3. The operation of these coils in compensating the retarding effect of capacity is as follows:—When the potential at a rises, current begins to flow through the self-inductive coil $a\,b$, and this current tends, by the well-known inertia-like action of self-induction, to go on after the applied electromotive force producing it has begun to diminish, or has even stopped or reversed. Hence the current in the self-induction coil $a\,b$ will attain its maximum value at a time after the potential at a has began to fall. It will by that very circumstance, as a consequence

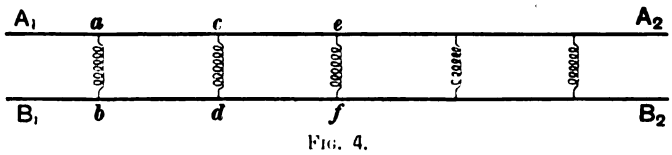

Fig. 4.

of the electromagnetic momentum, tend to make the potential at a fall *sooner* than it otherwise would do. Hence the respective actions of the self-induction coil and of the condenser are of opposite kinds. One tends to cause the changes of potential in the line to occur *later* than they should occur: the other tends to cause the changes of potential to occur sooner than they otherwise would occur. Hence their action tends to compensate one another if applied at the same place. But the capacity of a line or cable is not at one place; it is distributed all along it. Therefore it is essential that the compensating devices should also be placed all along it, at sufficiently frequent intervals. It is well known that Varley employed an inductive shunt *at each end* of a cable; but this is not capable of compensating the capacity, except within, at most, a few score miles of the ends. The coil $a\,b$ (Fig. 3) may be looked upon as compensating the capacity on both sides of it to a certain distance; the coil $c\,d$ as compensating the capacity on both sides of it; and so forth. If all these compensators are properly ranged along the cable, then the total retarding effect of the distributed capacity will be practically annulled. The currents that run in and out of the transmitting end will be greater in quantity than those that are delivered in and out at the distant end; the difference being of course accounted for by the currents that flow across through the compensating coils. It will be seen that by the use of these devices a certain fraction of the currents that are sent in at the transmitting end is, so to speak, used up on the way to pass through the compensating coils and by their action prevent the retardation of the rest of the currents that are flowing down the line. To put the matter tersely, the compensators act as leaks across from the A line to the B line, which by their inductive action sweep out the accumulating charges that would otherwise retard the signals. Some calculations on the magnitude of the currents that must thus flow across in the compensating coils have been made by the author, and some others for him by Dr. Sumpner. From these it appears that taking as a working basis the actual facts about cables as they are, and assuming a twin wire cable having a capacity of $\frac{1}{3}$ microfarad, and a resistance of 10 ohms, for a mile length, also assuming that compensating coils are placed across at every 10 miles, if such coils have a coefficient of self-induction of 100 henries and a resistance of 3,000 ohms

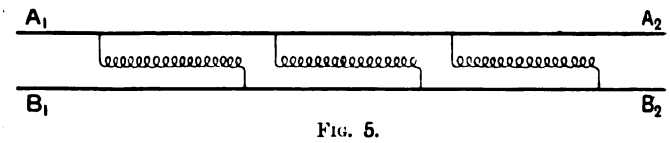

Fig. 5.

each (its time-constant being then about $\frac{3}{100}$ths of a second), the rise and fall of current in each section will, with currents of the ordinary telephonic periodicity, be practically instantaneous in each section during the very small fraction of a second that the impulse lasts; and the value of the current from section to section will be practically determined solely by the shunting action of the successive compensators. Now, as telephonic currents may be shunted down to an extraordinary degree of tenuity, and yet be perceptible, it is evident that there are great possibilities opened out by this method of using the shunted portions of the current to neutralise the retardation.

The cable so constructed of two wires with compensating devices shunted across at intervals of 10, 20, or it may be 500 miles apart, will be represented diagrammatically by Fig. 4. The practical problem then remains how to provide compensators having a sufficiently great time-constant without their constituting unwieldly enlargements of the cable. This is a very simple matter of construction. The author has tried several species of devices, some of them resembling elongated "hedgehog" transformers made very long and thin, and

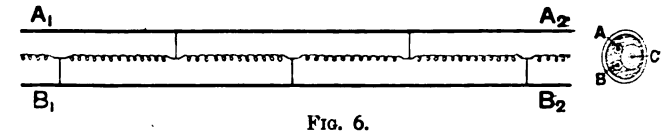

Fig. 6.

wound with one coil only of fine wire; others consisting of "shell" transformers elongated into a very long, narrow loop: others again consisting of simple iron wire, straight or looped, or of wire over-wound with a layer of iron wire. The self-induction, for example, of a one-millimetre iron wire, over-wound with a layer of iron wire three millimetres deep, is roughly about 0·1 henry per kilometre; and its resistance is 144 ohms. One point in favour of the use of loaded straight wires as self-induction devices is the circumstance that the compensator need not join two adjacent points in the two conductors within the cable, but may lie across as in Fig. 5. This construction, which is specially suitable for cables of moderate length, resolves itself into a three-wire cable, of which one wire is loaded in some way to give it self-induction and resistance, and is connected at intervals alternately to the other two, as in Fig. 6.

As stated above, however, not only by self-induction but by mutual induction, the retarding effects of capacity may be neutralised.

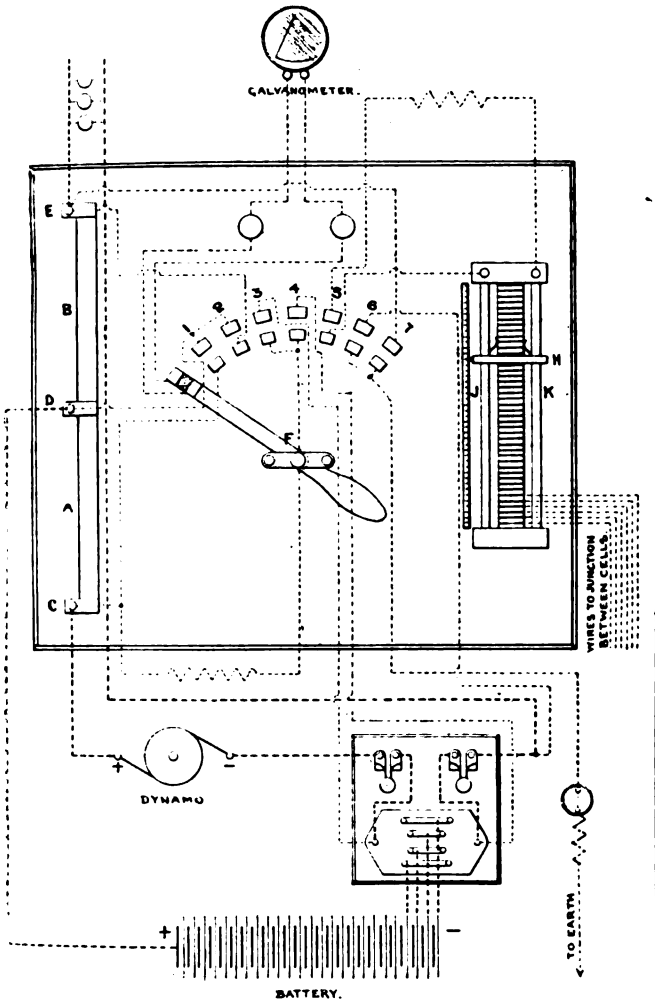
APPARATUS FOR THE COMPLETE TESTING OF A BATTERY OF SECONDARY CELLS.

The object of this apparatus is to provide an accurate and convenient means of making complete and rapid electrical tests of a battery of secondary cells such as is used in lighting a private house, or in central stations for electric supply. Only one instrument, the Holden-D'Arsonval galvanometer with a 10-turn coil, is used for all the tests, and no other ammeter, voltmeter, or cell-tester is required.

The apparatus (the internal arrangement and connections of which are shown in the accompanying figure) consists of a



case with glazed front containing the switches and resistances, which can be placed wherever convenient, either near to or some way away from the batteries, without in the least affecting its accuracy or efficiency, and a Holden-D'Arsonval galvanometer, as already described, with lamp and scale (see *The Electrician*, Vol XXXI., p. 257). The case will be seen to contain on its left-hand side a strip of platinoid A B, of suitable proportions for the maximum charging and discharging current; in the centre a double-pole switch, having seven positions; and on the right an individual cell-tester switch, which enables each cell in the battery to be tested for E.M.F. separately. The diagram shows the connections of the various portions of the apparatus, and the letters on this diagram correspond to those on the diagram of the actual apparatus. Position 1 of the switch measures the current leaving the dynamo in the following manner:—

The + pole of the dynamo is connected to C, and the + pole of the battery to D, the + main to the lamp being connected to E. Now, the double-pole switch when in position 1 connects the galvanometer wires direct to the points C and D, and, therefore, the galvanometer measures the fall of potential between the points C and D due to the charging current to which the fall of potential is proportional. This gives, therefore, a measurement of the current leaving the dynamo. In position 2 of the switch the galvanometer terminals are connected to D and E, and, therefore, the galvanometer measures the fall of potential between these points due to the current flowing to the lamps, otherwise the discharging current in the mains. In position 3 the terminals of the galvanometer are connected through a resistance of 50,000 ohms (for a 100-volt circuit) to the terminals of the dynamo, and thus a measurement is obtained of the charging E.M.F. In position 4 the galvanometer is connected in a precisely similar manner to the + and − lamp mains direct, so that the discharging E.M.F. is shown. In the fifth position the switch is connected through a resistance of 1,000 ohms to the bars J and K, which are in their turn connected to two springs underneath the sliding-piece H. Now, each of the rings of the switch being connected to the joint between one cell and the next one in the battery, it is obvious that in each position of the switch one cell only will be in circuit with the galvanometer. By means of a pointer attached to the sliding-piece H and the fixed scale, the instrument can be set with ease and certainty to measure any cell in the battery. The sixth position enables the insulation resistance of the + main to be measured by joining the + main to one terminal of the galvanometer, whilst the other is put to earth through a resistance and a fuse; and, finally, in the seventh position of the switch a direct measurement of the insulation resistance of the − main is obtained in a similar way. A suitable arrangement of scale and light for this apparatus is as follows:—The galvanometer is placed some 8ft. or 10ft. away from the scale, which should be about 10ft. long, and should have the various graduations in volts and amperes above and below the centre line. Immediately above and behind the centre of the scale is placed the lamp, the light from which shines through a slit $\frac{1}{4}$in. wide and about 3in. long—through a 2$\frac{1}{2}$in. or 3in. lens—to the galvanometer mirror, whence it is reflected back on to the scale, where it appears as a broad, vertical band of light. This band, if there is a line or wire across the lens, will be divided by a dark line serving as an index. The scale can be placed at a considerable height above the floor of the battery, or testing-room, and may conveniently be fastened to one of the walls. The galvanometer may be placed on a small bracket on the opposite wall, and the remainder of the apparatus placed in any available position. By this means the testing device can be made to monopolise but a small amount of useful space, and the floor of the room is left available for any other purpose. This convenient testing set is manufactured by Mr. J. Pitkin and supplied by Messrs. Drake and Gorham, agents for Major Holden's electrical instruments.

Rival Forms of the Clark Cell.—Dr. K. Kahle, of the Imperial Physico-Technical Institute at Charlottenburg, gives some further results of his comparative tests of Clark cells in the current number of the *Zeitschrift für Instrumentenkunde*. In his opinion the H form, as first suggested by Lord Rayleigh and subsequently modified by himself, is the best for permanency and facility of transport and reproduction. The Board of Trade form, where both the electrodes enter through the stopper, shows irregularities sometimes amounting to 1 per cent., which he attributes to want of saturation of the zinc sulphate solution at some points of the surface of the zinc, and also to the passage of small particles of zinc through the paste into the mercury. The substitution of cadmium for zinc he regards as a promising innovation, but with certain precautions there is no reason why the Clark standard cell should not supersede the silver voltameter as a calibrating instrument for galvanometers and other purposes. Commercial zinc does not contain any positive metals capable of sensibly affecting the electromotive force of the cell; but more negative substances, like arsenic, are apt to give rise to bubbles of hydrogen, which introduce a high resistance. The zinc should be well amalgamated, and the zinc sulphate solution perfectly neutral. Allowing for temperature cofficient, which has been accurately ascertained, the majority of the instruments constructed at Charlottenburg have been found reliable to within 1 part in 10,000.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; and Sir James Anderson, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

AVERAGES.

Trustworthy statistics are the foundation of many a successful engineering enterprise, and in the preparation of schemes for the supply of towns with electric light, the average number of lamps per house or per inhabitant, the average number of hours of lighting per day, the average length of mains, and a dozen other numerical expressions of great simplicity, but of grave importance, are freely quoted. Our New York contemporary, the *Electrical World*, has, however run foul of the engineering practice of striking an average. "Nothing is more dangerous," it says, "from a business point of view than dependence on the average; the average cost per horse-power of water power, steam or electrical machinery, and the numerous other tables of approximate information are often worse than useless, as an estimate based on them alone must in most cases be either too high and thus cause the loss of a contract, or, what is worse, will be too low and cause a direct financial loss." This is all very well; but there are averages *and* averages, and everything depends on taking the correct one.

The word average is used loosely to cover several distinct statistical processes, whereby a single numerical expression represents a generalisation from two or more data. If the data may, from a certain point of view, be considered to be

Digitized by Google

essentially similar, but to differ among themselves by accidental quantities, the process of striking an average tends to eliminate these accidental quantities, the degree of elimination being proportional to the square root of the number of data. But when the data cannot be regarded as essentially similar, nor the differences as accidental, an average is often both useless and misleading. A man proposing to manufacture glow lamps, and wishing to find what candle is most commonly used, might learn that a certain supply company has 25,000 8-c.p. lamps and 12,500 16-c.p. lamps on its mains. To deduce from this that the average candle-power is 10·6 would be absurd, but such averages are often used. To describe the capacity of a central station by its average output is perfectly useless. The ratio of this average to the maximum output gives the load factor, a most useful quantity, but one that tells nothing whatever about the size of the station. The mean steam pressure of an indicator diagram cannot be found from a few measurements, unless SIMPSON's rule or some conditions as to the selection of these measurements be observed. The practice of applying false reasoning to true averages is, perhaps, even more common than that of obtaining misleading averages. It has been said, for instance, that as the average number of people who die in bed in the course of a year so largely exceeds the average number who are killed in railway accidents, a sleeping car is, therefore, incomparably more safe than a bedroom. Statistics are generally quite unpresentable to the public unless the data upon which they are based are reduced to averages, and where, as in prospectus-writing, companies' and other reports, and similar documents, it is sometimes desired to put forward certain views in the guise of statistics, averages are freely used and too often abused.

Dr. GUY, writing on medical statistics, observed that "averages are numerical expressions of probabilities; extreme values are expressions of possibilities." The condition of things expressed by the average may never occur, and there may be good reasons for its never occurring. The idea of an average includes the idea of deviation from the average value, and the full discussion of the mean deviation, and of the probable deviation, or error, as it is sometimes called, and of the number of decimal places to which the expression of the average should be carried, are matters of considerable importance, but seldom receive much attention. An average is a particular kind of mean, the arithmetic mean. Besides this, we have geometric mean, the complicated and pretentious "method of least squares," and then again there is the puzzling "square root of the mean square," *et hoc genus omne*. We have long ago pointed out that the plain and simple arithmetical average of 10 alternating amperes would, if commutated into a direct current, be considerably different from 10 simple continuous amperes; whereby—had the Board of Trade been unwary in its choice of an "average"—an unscrupulous person might have made unlimited profit by merely grinding round a small commutator. There is besides all these purely arithmetical averages the system of weighted averages. These had best be left to astronomers, physicists and other men of irreproachable rectitude, for the application of the weights must be a matter of judgment, and would be a dangerous weapon in the hands of a company promoter. For ordinary purposes the simple average, used rationally, based on data which are properly comparable, sufficiently numerous, and which do not differ too much among themselves, is the true average. The true average, in any case, is that one whose substitution for the variable would produce the same numerical result, and there can be nothing approximate, risky, or erroneous in taking the one of these in place of the other.

THE INCANDESCENT LAMP AND ITS MANUFACTURE.*

BY GILBERT S. RAM.

(Continued from page 421.)

The effect of flashing is threefold, as already explained. It alters the emissivity, the resistance and the thickness of the filament. It diminishes the resistance, and, usually, the emissivity, and increases the thickness. The effect of increasing the thickness is opposite to that of diminishing the emissivity. That is to say, increase of thickness means increase of candle-power and decrease of emissivity means decrease of candle-power. The reduction in resistance and the increase in thickness continue to proceed as long as the process is going on. The emissivity, however, is changed almost entirely within the first few seconds, after which it remains practically constant.

What the lamp-maker wants to know is what sized filament he must take in order to produce such and such a lamp. If he is making unflashed filaments the matter is very simple, and the dimensions are readily calculated. If, on the contrary, he wishes to flash his filaments, the conditions are complicated by the three separate effects just mentioned.

A formula for calculating diameters for flashed filaments, on the same lines as for unflashed ones, might here be given. Owing, however, to the necessity for the introduction of constants, on account of the difference in specific resistance of the filaments and the deposited carbon, it becomes too cumbrous for practical use, and is, therefore, omitted. Instead of using the formula, a number of different cases can be worked out separately, and the results plotted out in curves, from which any other sizes can be easily and quickly obtained. Such curves are shown in Figs. 19 and 20.

Having obtained the curves, they are useful in enabling us to do several things at a glance. For instance, a particular lamp is to be made and its current must be so-and-so. The curves show at once what diameters of filament may be taken, and how much they must be flashed in order to produce the result. If it is desired to give the filaments a definite thickness of deposit, there is one diameter alone which will answer the purpose. Suppose that it is desired to give a coating 0·3 mil thick. It takes 60 seconds to do this. Take the case of a 100-volt, 16-c.p., 0·64-ampere lamp. We find on the 60 seconds curve (Fig. 19), that we must take a filament 5·3 mils diameter to give this current. During the process of flashing it will become thickened to 5·9 mils, a fact which must be remembered in estimating its length. The length to be taken is given as before by the formula $l = b\frac{\text{c.p.}}{d}$, d being the finished diameter, the value of b in the case of the flashed surface being 2·8 (*i.e.*, the constant for the unflashed surface $\times \frac{14}{10}$, the ratio of the emissivities)

Therefore $$l = 2{\cdot}8 \times \frac{16}{5{\cdot}9} = 7{\cdot}6\text{in.}$$

7·6in. of 5·3 mils diameter filament must then be flashed for 60 seconds, and it will then be the right resistance and surface.

This, therefore, shows another way by which filaments may be flashed to the required resistance. No instruments are needed except a watch to show the time of flashing. Start with the proper size of filament shown by the curve, and flash it for the required length of time, and it is brought to the required resistance. Such a method, however, would not work well in practice owing to the difficulty of exactly reproducing to conditions each time. If, however, the right size of filaments, as shown by the curve, are taken and flashed to their proper resistance hot, the time of flashing will be 60 seconds on the average.

It will be seen by examining the curves that there is a wide range of possible sizes for the filament, according to the

* Abstract from a book to be published shortly by *The Electrician* Printing and Publishing Company (Limited). All rights of republication reserved.

Digitized by Google

amount of flashing it receives. For the same lamp taking 0·64 ampere, a filament 3·7 mils in diameter flashed for two minutes gives the required result, or one of 7·65 mils flashed for only ten seconds will do equally well.

It has, however, been pointed out that thirty seconds is about as long a time as can be allowed for flashing in practice. By taking the sizes given by the thirty-seconds curve we get always, for any current, the diameter which will take thirty seconds to flash to its required resistance.

On examining the curves, one thing that immediately attracts attention is that the curves for the flashed filaments D, E, F, G, H, J, cross the curve for the unflashed ones A, at some point. This is on account of the variation in the equivalent specific resistance of the flashed filaments.

The topmost heavy curve B shows what the result would be if the filaments could be flashed so as to give the less emissivity of the deposited carbon, but without changing the resistance. In other words, it is the curve for a carbon of the specific resistance of the unflashed, but with the emissivity of the deposited variety. It is introduced in order to show the limit of diameter for any current beyond which it is impossible to go under any conditions with these two qualities of carbon. In the other direction the limit of the diameter is zero; that is to say, the amyloid filament vanishes altogether, deposited carbon alone remaining.

6 mils being the diameter of a solid filament of deposited carbon alone. The lower heavy curve C gives the values for such material.

In order to make the matter as clear as possible the second sheet of curves (Fig. 20) is given, showing the final or flashed diameters. It will be noticed that all the sizes lie between the limits of the heavy curves B and C. It is, however, the diameters of the filaments before flashing that the lamp-maker requires in the first instance.

Looking at the curves (Fig. 20) we see for any current within what limits the final diameter of the filament for that current must lie. Thus, for two amperes the final diameter will lie between 8·2 and 17·7 mils. Theoretically, any diameter between these limits may be made to do for two amperes, according to the length of time of flashing, or no flashing at all if the filament be 15·9 mils, as shown by the dotted curve A.

In actual practice the limits are somewhat more restricted, on account of the difficulty of making or handling very thin filaments or of flashing properly in less time than 10 seconds. The practical limits for this current may, however, be considered as 10 mils and 17 mils finished diameter, still a very wide range, according to whether the flashing be done for 10 seconds or up to five or six minutes. This means that the filament before flashing will have a range of from 4 or 5 mils to 17 mils

Curve A gives diameters for currents up to 3 amperes for the usual quality of unflashed carbon.

FIG. 19.—Curves showing Relation between Current and Diameter of Filaments for Different Durations of the Flashing Process. (The diameters represent the measurement of the filaments *before* being flashed.)

Thus the diameter selected for a 1·25-ampere filament at the temperature of 4 watts per candle power may be anything from 12·9 mils down to nothing, according to the time of flashing. If unflashed carbon is used the diameter, as shown by the dotted curve A, will be 11·6 mils; if flashed for 10 seconds it will be 12·3 mils; for 20 seconds, 11·7 mils; for 30 seconds, 11·15 mils; for one minute, 9·7 mils; for two minutes, 7·5 mils. The limit of zero diameter is reached (supposing such a thing possible) at the ten-minutes' curve. It must be remembered that the diameters shown by the curves (Fig. 19) are the diameters of the filaments before flashing, and that the actual finished diameters are greater according to the length of time they are flashed by one-tenth of a mil for every 10 seconds. In the limit when the diameter of the unflashed carbon becomes zero the actual diameter is 0 + 6 mils, 6 mils being the increase in diameter produced in ten minutes. In other words, the filament is now entirely of deposited carbon, and 6 mils in diameter. Speaking, then, of the final or flashed diameter, the limits for 1·25 amperes are 12·9 mils and 6 mils, in diameter. If the time of flashing is to be restricted to 30 seconds then 16·05 mils will be the finished diameter and 15·75 the diameter before flashing.

The fact that flashing a filament may *reduce* as well as increase the current strength necessary to raise it to a given temperature, is one which the author believes to be not generally realised. Looking at the curves for finished diameters, it is seen that an unflashed filament of 14 mils diameter takes about 1·66 amperes. A filament of this diameter which has been flashed for ten seconds takes only 1·49 ampere. One which has been flashed for twenty seconds takes 1·58 ampere, while one flashed for thirty seconds takes 1·66 ampere, the same as the unflashed one of that diameter. If flashed for a longer time than thirty seconds it takes more current than the unflashed one.

When the diameter and current are the same for unflashed and flashed, as in this case for fourteen mils and thirty seconds, the lengths of the filament to produce the same volts and candle-power will be in the proportion of ten

Digitized by Google

to fourteen, the length of the flashed filament being greater in inverse proportion to the alteration in emissivity.

Looking at the curves showing the diameters *before* flashing we see that an unflashed filament of 16·8 mils diameter takes 2·18 amperes. If this same filament be flashed for ten seconds, it takes only 1·97 ampere, if it be flashed for twenty seconds it takes 2·07 amperes, and if for thirty seconds it takes 2·18 amperes, the same as it did before being flashed. Its diameter is, of course, increased by 0·3 mil and is 17·1 mils.

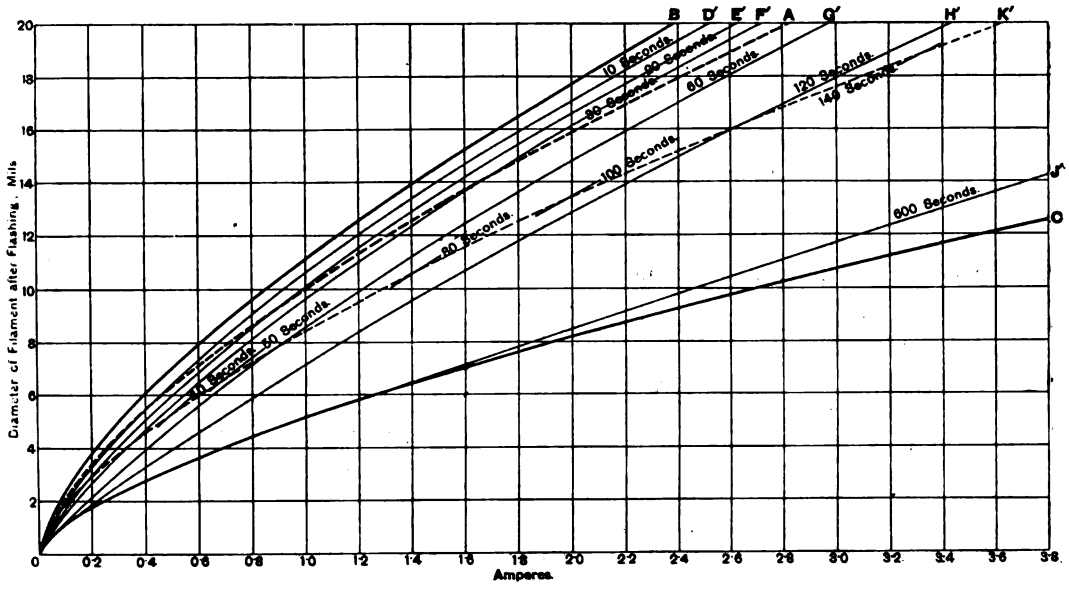
Here, again, let there be no misunderstanding about efficiency. The filament, flashed for a short time and which takes less current and fewer volts than it did before flashing to maintain it at a certain temperature, is no more efficient than before flashing. The power required to produce the temperature is less. In precisely the same proportion is the candle-power also less.

When filaments are flashed to a certain resistance measured cold, it has already been pointed out, that owing to the widely different temperature coefficients of the filament and the deposited carbon, it is essential that the ratio of the two amounts of these carbons present in the filament be known. In a factory where the cold measurement is adopted it should be a rule always to flash the filaments so that there is a fixed ratio between the sectional area of the filament and that of the deposit, that is to say, between their resistances.

It has been mentioned that the general formula for diameters of flashed filaments is too cumbrous for ordinary use, owing to the difference in the specific resistance of the two kinds of carbon having to be taken into consideration. When, however, there is a fixed ratio between the quantities of the two kinds of carbon in the filament, the formula becomes of the simple form, $d = a\,c^{\frac{2}{3}}$, where d is the diameter of the filament, c the current, and a is a constant, the value of which depends on the specific resistance of the filaments, the emissivity, the units employed, and the temperature at which the filaments are to be run. In order, then, to find the right diameters to use, so that there shall always be a fixed ratio between the resistance hot and the resistance cold, it is only necessary to find the value of the constant a for whatever ratio is required, and the formula gives the required result.

If we arrange matters so that the cold resistance is for all diameters twice the hot resistance, then, having determined the corresponding value of a, we shall find that the curves K and K′ (Figs. 19 and 20) give the diameters before and after flashing. Supposing, then, that the filaments are flashed until the resistance measured cold is brought down to the value of twice the required resistance hot, we can at once find the diameter for any current from these curves, and we can also see the time which will be occupied in the flashing by the crossing of the curve with the time curves D, E, F, G, &c.

In many lamp factories, the sizes of filaments and the amount of flashing they receive are regulated entirely by guess and trial methods. Such methods, no doubt, answer the purpose in the end just as well as a calculation by a formula, or information obtained from a curve. But by a proper understanding of the effects produced by alterations in the diameter of the filament or the time or conditions of the flashing, the required results can be much more certainly and quickly obtained. Of course, it is impossible to get lamps all *exactly* right by any method. There are too many causes at work to upset the calculations, too many variable conditions to be simultaneously taken into account. Nine out of ten of the things to be considered may be right, the tenth one being wrong throws the combined result wrong. It is, however, only by taking everything into consideration that good results can be expected.



D′ has been flashed for 10 secs., and is 0·1 mil thicker than before flashing.

Fig. 20.—Curves showing Relation between Current and Diameter of Filaments for Different Durations of the Flashing Process. (The diameters represent the measurement of the filaments *after* being flashed. A, B, and C are the same curves as on Fig. 19.)

A good instance of the happy-go-lucky methods sometimes used was seen a few years ago by the author in a factory, where the filaments were flashed in an apparatus, using an automatic cut-off, which stopped the current when it attained a certain value. This cut-out was a very crude affair, and was not at all particular as to when it went off. The flashing globes were allowed to get so black that the operator could not possibly gauge the temperature of the filament, and the consequence was that the cut-off would "act" just when the operator chose to turn the current up sufficiently. After this process the filaments were "selected" by measuring their resistance cold, a range of about twenty per cent. being allowed. The result was that three-fourths of the filaments were rejected. Of those that came within the limits of the resistance cold, perhaps one-third would be of the right resistance hot, which was always assumed to be half the cold resistance. The proportion of lamps of the proper voltage was, of course, extremely small, while the percentage of filaments which became lamps of the right voltage was microscopical.

Digitized by Google

The factory above alluded to was, luckily, situated in a country where very badly-matched lamps could be sold as of the same voltage. Any one who visits the Continent at the present time will, with a very slight observation on the lamps to be seen in use, be convinced that kindred methods must still be in use in a good many factories. The unfortunate part of it is that this country, before another year is over, is likely to be flooded with these foreign badly-matched lamps, which people will buy on account of their cheapness.

DYNAMO SHIELDING.

BY W. H. M. CHRISTIE (ASTRONOMER ROYAL).

The proposed establishment of a system of electric lighting at the Royal Observatory, Greenwich, made it necessary to consider the possible disturbing effect of a dynamo on the magnets of the Magnetic Observatory, and how far the influence thereof could be diminished by any system of shielding.

Messrs. Johnson and Phillips, of Old Charlton, having been selected to supply the electric light installation, they very kindly undertook to give facilities for carrying out, at their works, such experiments as were considered necessary, and it is due to the valuable assistance so given that a satisfactory protection of the magnets has been arranged.

From the general interest felt in the subject of shielding, it may be interesting to give here an account of the experiments made. Protecting shields of various sizes having been prepared by Messrs. Johnson and Phillips, the effect of different combinations of shields was tried, employing in all cases the dynamo actually constructed for use at the Royal Observatory, which is to give 2 kilowatts with 130 volts. The dynamo in the experiments was, for convenience, driven as a motor by a current of 130 volts, and the shunt-wound single-horseshoe field-magnet was excited with 80 volts, a resistance being interposed in the shunt to reduce the intensity of the magnetic field.

The disturbing effect of the dynamo when unshielded was in the first instance measured. For this the dynamo was arranged with poles in an easterly and westerly direction (magnetic), a delicately suspended magnetic needle, that of a Kew unifilar, insuring accuracy of measure, being mounted at two different distances west (magnetic) of the dynamo. In this disposition of the apparatus (with the needle east or west of the dynamo) the maximum disturbing effect at a given distance is obtained. Measures were made on March 9th last as follows:—

Distance of magnetic needle west of dynamo.	Deflection of needle, dynamo not shielded.
Feet.	
20	168′ 40″
40	23′ 40″

The reading of the suspended needle was usually taken in reversed positions of the dynamo poles, the angular deflection given being the half difference of the extreme readings.

Practically, the disturbing effect of one magnet on another will vary (the relative positions being the same) as the inverse cube of the distance, provided that the distance is large as compared with the size of the magnets. On this understanding, the observed angles being small, the deflection measured at 40ft. should be one-eighth part of that measured at 20ft., or should be 21′ 5″; the observed value is 23′ 40″, showing that for the dynamo the ordinary law sensibly applies.

Three shields of different sizes, made of ¼in. iron plate, each one being in the form of an arch (with open sides) were employed; they were placed over the dynamo with their open sides in the direction of the dynamo axis, that is north and south, and two or more shields could be in position together, there being a small air space between each. Side pieces of similar plate iron were also prepared, which could be added at pleasure on either side of the arch.

The following measures (also on March 9th) were made, the magnetic needle being distant from the dynamo 40ft. west, and the poles of the dynamo in an easterly and westerly direction as before, which was indeed the position of the dynamo poles throughout the experiments:—

Arrangement of protecting shield.	Deflection of needle, dynamo shielded.	
	Shield without sides.	With sides.
Large shield only.....	9′ 30″*	8′ 16″
Small shield only	6′ 46″	5′ 22″
Small and medium shields.....	5′ 32″*	—
All three shields	3′ 42″	3′ 15″

The measures marked thus * were made in one position only of dynamo poles.

The results in the first column indicate that the shielding effect is generally greater the nearer the shield is to the dynamo. The best effect is produced by use of the three shields with side pieces, the deflection being thereby reduced from 23′ 40″ (the value with dynamo unshielded, at 40ft.) to 3′ 15″, or to a one-seventh part.

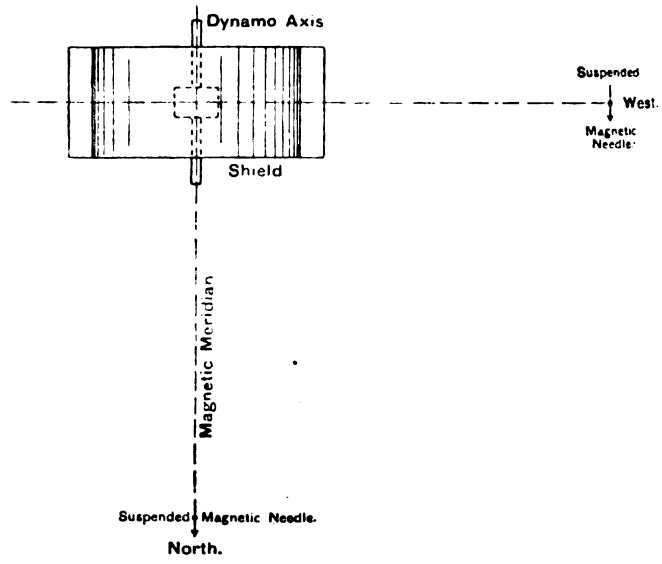

FIG. 1.—Plan showing Arrangement of the Apparatus.

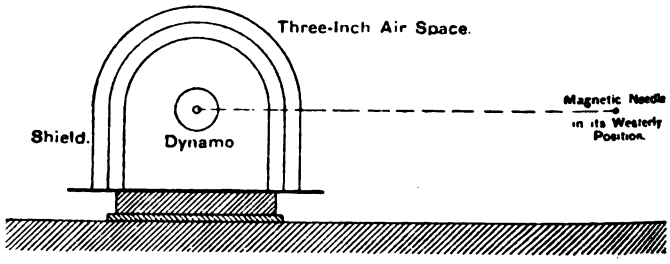

FIG. 2.—Section in an East and West Direction through Shield and Dynamo.

The three shields were now attached all to one base plate, thus forming a triple shield, entirely closed on one side, but with a necessary partial opening on the other, the dynamo being in the centre of the inner shield. The horizontal diameter of each of the three shields is 28in., 34in., and 40in. respectively, and their height from base plate 31in., 34in., and 37in. respectively, the air space between adjacent shields being thus about 3in.

With the triple shield as thus prepared, further experiments on May 31st were made:—

Distance of magnetic needle from dynamo.	Whether needle was west or north of dynamo.	Deflection of needle.	
		Dynamo shielded by triple shield.	Dynamo not shielded.
Feet.			
20	West.	24′ 58·5″	—
40	West.	2′ 45·2″	19′ 38·0″
60	West.	0′ 54·4″	—
40	North.	1′ 1·8″	9′ 20·8′

Digitized by Google

By the already mentioned law the deflection at 40ft. should be one-eighth of that at 20ft., or one-eighth of 24′ 58·5″ = 3′ 7·3″ The observed value is 2′ 45·2″ And the deflection at 60ft. should be $\frac{1}{27}$th part of that at 20ft., or 55·5″, the observed value being 54·4″. Again, the deflection at a given distance, with needle north, should be approximately one-half of that with needle west. Half of 2′ 45·2″ is 1′ 22·6″, the observed value being 1′ 1·8″, and half of 19′ 38·0″ is 9′ 49·0″, the observed value being 9′ 20·8″ On the whole, the observed results follow satisfactorily the ordinary law.

So much for consistency of the results. As regards the other important point, the influence of the shield in diminishing the disturbing effect of the dynamo, we have now the following results :—

Day.	Magnetic needle west or north of dynamo.	Deflection of needle.		
		Dynamo not shielded.	Dynamo shielded by triple shield.	Reduced by shielding to
March 9 ...	West	23′ 40·0″	3′ 15·0″	$\frac{1}{7}$th part
May 31 ...	West	19′ 38·0″	2′ 45·2″	$\frac{1}{7}$th „
„	North	9′ 20·8″	1′ 1·8″	$\frac{1}{9}$th „

Distance of magnetic needle from dynamo = 40ft.

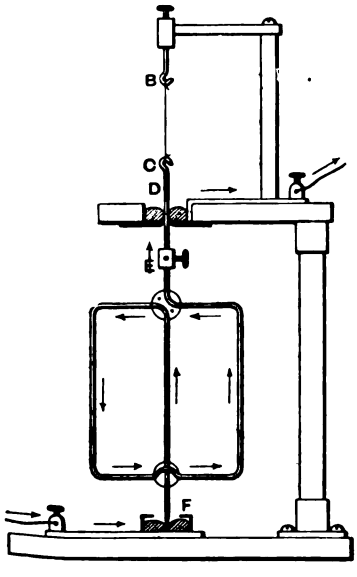
These results were arrived at with essentially the same condition of shield, the only difference being that on March 9th, the parts of the shield were not attached, whilst on May 31st the experiments were made with the completed shield.

The reduction of the disturbing effect of the dynamo thus produced is eminently satisfactory. At the distance at which it is proposed to place the dynamo from the magnets at the Royal Observatory the influence of the dynamo (when shielded) on the declination magnet would be reduced to about half a second of arc, and to a correspondingly insignificant amount also for the horizontal force-magnet.

The experiments were carried out by Messrs. Ellis and Nash, of the Royal Observatory, with the co-operation of Messrs. Johnson and Phillips.

A NOVEL ARRANGEMENT FOR AMPERE'S TABLE.

At the annual exhibition of the Société Française de Physique M. Nodot exhibited a novel arrangement of Ampère's table, in which, owing to the very low friction of the moving parts, the action of the magnetic field of the earth and of magnets and currents upon conductors carrying currents, can be shown without the use of any very considerably large forces. The apparatus is represented by the accompanying figure, in which the movable conductor, which has to turn on a vertical axis, is suspended from a fixed hook, B, by means of a silk thread, BC. The lower end of this thread is fastened to a hook in a platinum wire, D, which passes through a small circular hole in a disc of mica with sufficient clearance to prevent friction due to the rotation of the platinum spindle. This mica disc forms the bottom of a mercury cup, as shown in the figure; and the contact of the mercury with the platinum enables the current to pass from the movable conductor. The lower end of the movable conducting frame dips into a second mercury cup, F, in the base of the instrument, by which means the current can be conveyed into the frame. By means of a coupling screw, E, it is possible to disconnect the conducting frame from the suspending wire and thread, and to substitute any other shape of frame that may be desired. It will be seen that, by means of the arrangement described, there will be but a very small amount of friction at the pivots, while the torsion of the silk thread will oppose only a feeble resistance to rotation. The capillarity of the mercury prevents it from creeping through the clearance space between the edge of the circular hole in the mica and the platinum spindle, for mercury does not wet or amalgamate with platinum. It seems not improbable that a delicate adjustment of a suspended coil, such as this one of M. Nodot's, might be useful in galvanometer construction.



THE PRACTICAL MEASUREMENT OF ALTERNATING ELECTRIC CURRENTS.

BY PROF. J. A. FLEMING, F.R.S.*

1.—The Measurement of Alternating Current Strength.

The subject on which I have undertaken to speak in this and three succeeding lectures is the practical measurement of alternating electric currents. The limits of time at our disposal will not permit me to deal with the question of electric measurements in general, far less to discuss the elementary principles on which all such measurements depend. I shall take it for granted that you are, at any rate, familiar with the fundamental facts concerning the production of electric currents, and most, if not all of you, familiar with the processes and instruments used in the measurement of continuous or unvarying currents.

The measurement of alternating or periodic currents involves processes and ideas which are somewhat more difficult to master than the simple conceptions which are sufficient to guide us in dealing with unvarying currents. It is towards the elucidation of these special difficulties that these lectures will be directed; and, keeping in view the special requirements of practical engineers dealing with alternating currents, I shall address myself entirely to the practical question of measurement, leaving out of account altogether theoretical matters. The practical measurement of alternating currents is a very important subject, because probably by far the larger portion of the electric lighting of the world is now conducted with alternating currents, and some of the largest schemes of transmission of power that are in process of development or already completed, are being carried out by means of alternating currents.

Our first duty will be to begin with some familiar definitions which will make clear the meaning of the terms to be employed. When a conductor is traversed by an electric current we know that certain physical effects are produced. We know nothing about the real nature of an electric current. All that we can do is to measure the degree or amount of the physical effects it produces. Two of these effects are at once evident on very simple investigation, namely, that the current heats the conductor and produces around it a magnetic field. The moment we begin to investigate these effects we find that the electric current may be either in a variable state in which progressive changes are taking place in the effects produced by that current, or it may be a steady or unvarying condition in which the effects remain constant; or it may give evidence of being periodic in its nature, that is to say, the electric current may vary in strength and in direction in a periodic manner. When any cycle of operations takes place in such a way that any given effect runs through a series of changes, we speak of the periodic time of that effect, meaning by that term the time in which the whole cycle of operations is completed. Also we speak of the frequency of the change, meaning by that term the number of cycles completed in a second. A familiar illustration of the use of these terms may be drawn from music. In the case of a musical sound, the string, or the air in the pipe runs through a certain cycle of

* Abstract of Cantor Lecture delivered before the Society of Arts, January, 1893.

Digitized by Google

movement, and the periodic time of the note is the time of completion of one complete vibration of the string or of the particles of the air; the frequency is the number of complete vibrations per second. The middle C of the piano has, or may have, a frequency of 256, the octave below that 128, the octave below that 64. In the case of electric currents which are periodic, the strength of the electric current is changing from instant to instant, and it is periodically reversed in direction. Applying the above terms, we speak of the frequency of the current, meaning the number of complete cycles in a second. For instance, the alternating current supplied from Deptford has a frequency of about 84, which corresponds to the lower F on the bass clef. The currents employed in the electric lighting of Rome are about an octave lower, namely, 40 in frequency.

You may picture to yourselves the difference between a continuous and an alternating current as similar to the difference between a non-tidal and a tidal river. In the case of a non-tidal river the waters flow on always in one direction—down the river; but in the case of a tidal river, such as the Thames at London Bridge, the direction of the flow of the water is periodically reversed. When we are dealing with periodic currents, or periodic E.M.F.'s, it is very convenient to represent these by means of current curves, or E.M.F. curves. To do this we take a horizontal line to represent the periodic time of the current, and dividing this line into a number of small equal parts, we erect perpendiculars at each point, proportional to the strength of the current, or to the E.M.F. at that instant. Joining the tops of these lines by a curve we have an E.M.F. or current curve. We then may speak of the instantaneous value of the current or E.M.F., meaning thereby the value it has at any instant; or we may speak of the mean value of the current or E.M.F., meaning thereby the average value which it has during the period. It is also necessary to consider another, a rather more complicated kind of average, which is called the square root of the mean square value. This is obtained by taking the mean of the squares of all the instantaneous values taken at the equidistant intervals during the period, and then taking the square root of this mean value. To avoid constant repetition of this cumbersome phrase, the square root of the mean of the squares of the equidistant values during the period, we shall call it shortly $\sqrt{\text{mean-square}}$ value of the current or E.M.F.

Presently we shall see why it is that certain instruments give us this $\sqrt{\text{mean-square}}$ value. It is important, sometimes, to be able to draw these current curves for any alternating current, and this has been done by many observers, notably by Duncan, Ryan, and Hopkinson.

In Fig. 1 we have a diagram of an apparatus used for this purpose by Dr. Hopkinson. On the shaft of an alternator is placed an ebonite disc, having at one point on its circumference a narrow feather of brass laid in. As the ebonite disc is carried round by the machine, the brass edge is made to complete the circuit between two metallic brushes, which press against the ebonite disc, and the instant when this occurs can be determined by varying the position of the brushes. By connecting an electrometer with these brushes in the manner shown in Fig. 2, the electrometer gives us the measure by its deflection of the instantaneous value of the E.M.F force of the machine at that one particular instant. By shifting the position of the brushes we can measure the E.M.F. at equidistant intervals during the period, and then plot out the E.M.F curve. In the same way, by measuring the instantaneous value of the potential difference between the ends of the resistance traversed by an alternating current, we can delineate the form of the current curve for that particular current.

We have, in the next place, to understand what it is that we are able in general to measure in dealing with alternating currents. When the alternating current flows through a wire we may, by means of the instrument above described, determine the instantaneous values of that current. But this is not what, in general, we wish to do, neither are we much concerned with the true mean value of that alternating current. In by far the larger number of cases the only thing that we want to know, and the only thing that we are able to measure, is the $\sqrt{\text{mean-square}}$ value above explained.

When an electric current flows through a wire it heats it, and the rate of production of heat is any instant proportional to the square of the current strength. Hence, if the current strength is changing from instant to instant, the total quantity of heat produced in the wire in any given time is proportional to the mean of the square of the current strength. Under fixed conditions, the temperature which the wire will assume will depend upon this mean square value of the current; for the wire attains its final temperature when there is a balance between the rate at which the heat generated in it and the rate at which the heat has lost by it. The wire loses heat in three ways—by convection, by radiation, and by conduction. If a wire is enclosed in a tube in such a way that convection is prevented, then the wire attains a final state of temperature, when there is a balance between the rate at which the wire loses heat by radiation, and gains it by internal generation. Under these conditions the temperature, and therefore the length of the wire, is determined, not by the average, but by the mean square of the current strength. If, therefore, the current is an alternating current, the final temperature and therefore the length of the wire enables us to measure this mean square value of the current. In the same way if two conductors, one of which is fixed, and the other movable, are traversed by the same electric current, the electro-dynamic repulsion or attraction between these two conductors, due to the magnetic field around them, becomes a measure of the some mean square value of the current, for at any instant the stress between the conductors is proportional to the square of the current strength flowing through them, and if the current is varying from moment to moment the average value of this stress is a measure of the mean of the square of the current strength. We may therefore employ either of these two physical effects, the heating of a wire by a current, or the mutual stress between two conductors traversed by the same current, to measure the mean-square value of that periodic current.

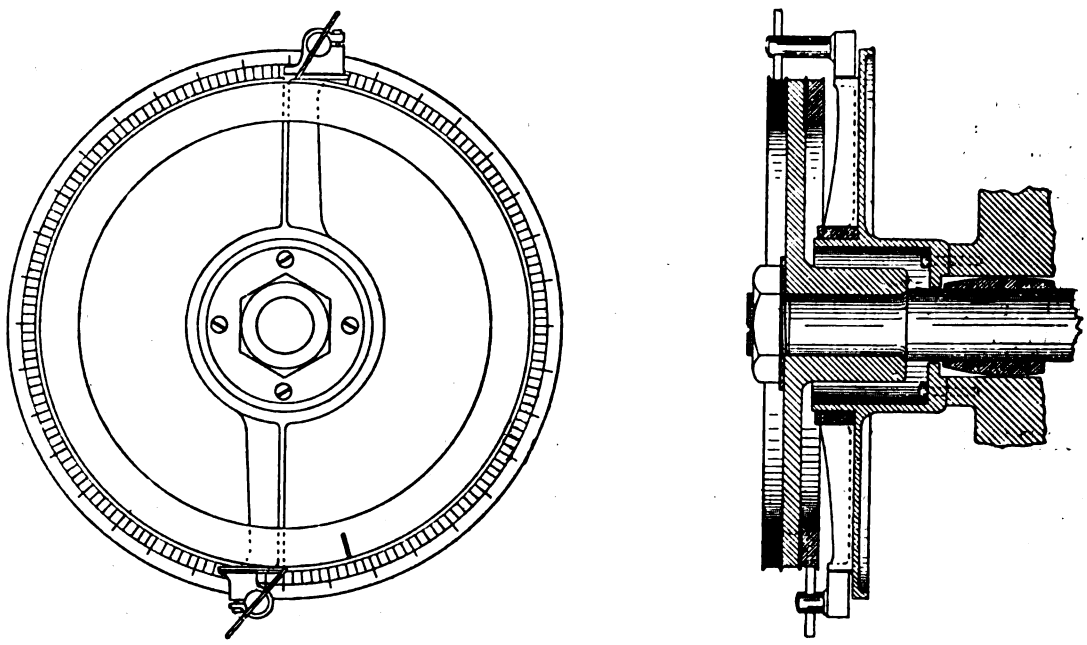


Fig. 1.

So much being understood, it is now possible to point out to you what we mean by an alternating current of one ampere. A continuous current of one ampere has been defined by the Board of Trade Committee as an unvarying current of electricity which, when passed through a solution of silver salt, deposits 0·001118

Digitized by Google

gramme of silver per second, or 4·9248 grammes per hour. This may be taken as the practical definition of what is meant by an electrical current having a strength of one ampere when that current is an unvarying current. An alternating current cannot, however, be estimated by such an electro-chemical method, but it is defined as follows:—An alternating current of one ampere is understood to be a periodic current which, when passed through a conductor, brings this conductor to the same final steady temperature as an unvarying current of one ampere would do when passed through it under the same conditions. It is, therefore, an alternating current whose √mean-square value is unity, assuming the instantaneous values to be measured in fractions or multiples of an ampere. Having defined our unit of alternating current, and the two particular general methods of the √mean square value, I may show you two experiments illustrating these facts.

Fig. 3 represents an instrument which I have designed for some other purposes, but which is practically an apparatus for the measurement of the expansion of a wire. It consists of a wooden stand, A B, having a sliding rod, *a*, at one end, pushed forward by a micrometer screw, M, and at the other end a system of levers,

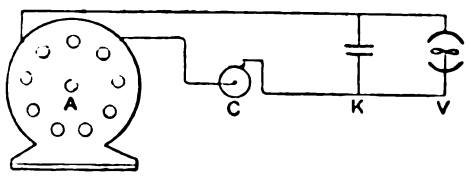

Fig. 2.

c, *d*, *e*, moving a mirror, *m*, from which a ray of light is reflected on to the screen. The micrometer rod and the system of levers are connected by a very fine copper wire, *w*, about 15in. long. On passing a continuous current of electricity through the wire, the spot of light on the screen changes its position, indicating that the wire has elongated. I can then, by means of the screw, bring the spot of light back to its old position, and thus measure the elongation of the wire, and therefore its mean temperature. Performing then the same experiment with an alternating current, which is adjusted to give the same expansion to the wire, I know that I have now passing through the wire an alternating current, of which the √mean-square value is equal to the value of the continuous current. Such a thermal instrument may be modified in many ways, and we shall presently see the forms it assumes; but in all of them the same principles are, in practice, employed.

In the next place, let me direct your attention to another apparatus, intended to illustrate the electro-dynamometer method of measuring alternating currents. An electro-dynamometer is an instrument which consists of two coils of wire, one of them fixed and the other movable. The movable coil is placed with its axis at right angles to that of the fixed coil, and when one and the same

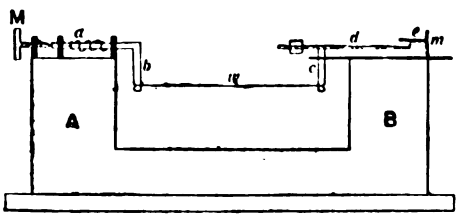

Fig. 3.

current is passed through the coils, the movable coil tends to turn round so as to place its axis in line with that of the other. But by twisting round the suspending wire we can bring the coils back to their original position, and this amount of twisting is a measure of the mean square value of the current strength flowing through the coils. If, therefore, the current varies from instant to instant, the force which is required to hold the movable coil in any given position varies as the average of the square of the strength of the periodic current. Hence, by means of these instruments, as by means of the hot-wire apparatus, we can measure the mean square value of the periodic current. Whilst speaking of this instrument, I will point out one fact which is of practical importance. We know that if a copper plate is held in front of an alternating electromagnet it is repelled, and similarly, if a copper plate is held near the movable coil of this dynamometer, it in like manner repels the movable coil when that movable coil is traversed by an alternating current. I shall afterwards have to point out the practical importance of this fact.

Before going on to discuss in detail various classes of practical instruments which depend upon the principles just explained, it may be convenient to give here a brief classification of electric measuring instruments. The table below will show that these instruments may be classified into six divisions, depending on the kind of quantity they are intended to measure. They may also be classified into five species, depending on the particular physical principle which is employed in the instruments. It is not, however, every one of all possible varieties of such instruments that exists. Those instruments which have practically been made are indicated by an asterisk in the table below:—

	Electro-dynamic.	Electro-magnetic.	Electro-thermal.	Electro-chemical.	Electro-static.
Ammeters or current meters	*	*	*		
Voltmeters or pressure meters	*	*	*		*
Ohmmeters or resistance meters		*			
Coulomb meters or quantity meters				*	
Erg meters or energy meters	*	*			
Watt meters or power meters	*	*			*

Taking, then, the first species of instruments, namely, those depending on electro-dynamic force, I will proceed to describe the valuable instruments invented by Lord Kelvin. Broadly speaking, these instruments may be described as electro-dynamometers, in which there are four fixed coils, around or between which are placed two movable coils attached to a balance arm. The particular point to notice in these instruments is the manner in which the balance arm which carries the movable coils is suspended, so as to permit the coil to move freely, and will enable us to get the current into and out of the movable coils. Lord Kelvin solved that problem by the highly ingenious arrangement of suspending the balance arm by a large number of very fine copper wires. These flexible ligaments of copper are fixed at one end to a pair of fixed copper trunnions, and the other ends to projecting copper lugs attached to the balance arm. When the balance arm is in equilibrium the movable coils occupy a position between the fixed coils, and the connection of the circuits is such that the current can be passed through the whole of the coils in series. When this current so passes it brings into existence forces of attraction and repulsion between the fixed and movable coils, and the balance arm is tipped over in one direction. Equilibrium can then be restored by moving a sliding weight along a tray attached to the balance arm, and when the balance is obtained the position of this weight can be read by means of a scale. By the principles above explained the force required to hold the beam in its position of equilibrium is proportionally to the square of the current strength, and accordingly the beam can be graduated in such a manner as to read off currents directly.

In accordance with what has been above said, it is necessary, when these balances are used for alternating currents, to avoid bringing any metal piece into contiguity with the coils. Accordingly the base of the balance is made of slate, and the coils wound on either slate or porcelain bobbins, or on some material which is a non-conductor. The balance is calibrated for use by means of a steady current, and it is then available for use with alternating currents. Lord Kelvin has devised a whole series of these instruments, which are capable of measuring currents from $\frac{1}{1000}$th of an ampere up to 1,000 amperes, and each instrument has a range of about 1 to 100.

A reference has already been made to the electro-dynamometers of Siemens, which are illustrated in Fig. 4. In all these dynamometers there is a fixed coil and a movable coil, both of which are traversed by the current to be measured. The current is got into and out of the movable coil by means of mercury cups, and the movable coil is brought back to its normal position when diplaced by the current by means of the torsion of a spiral spring. Another instrument of the electro-dynamometer class, but involving a slightly different principle, is one which I devised many years ago, and which depends on the principle of the repulsion of a copper disc by an alternating current. In this instrument there is a fixed coil of wire, which is traversed by the current to be measured. In the interior of this coil of wire there is a small copper disc, which is suspended by a fine wire. The disc is so placed that in its normal position its plane is inclined at an angle of 45deg. to the axis of the corner. When an alternating current is sent through the coil the copper disc turns round so as to place its plane in the direction of the axis of the coil. The torsion of the wire resists this movement, and the copper disc takes up some position of equilibrium. An instrument of this kind can be made to measure very small alternating currents, such as those of about one-thousandth of an ampere. Quite recently I have determined the law of deflection of this instrument, and I find that the angular displacement of the disc from its position of equilibrium is closely proportional to the square of the current strength passing through it. By attaching a mirror to the copper disc, the angular movements can be very much magnified, and the instrument then becomes available for detecting small alternating currents.

Digitized by Google

We must next pass on to consider instruments which depend on electromagnetic action, and in order to understand the principles on which such instruments act, we must investigate one or two elementary facts with regard to the behaviour of iron in a magnetic field. If I place a small coil in a horizontal position in the field of an optical lantern, and in the centre of that coil I suspend a small fragment of iron ; on passing an alternating current through the coil, the piece of iron is drawn away from the centre of the bobbin, and moves up against the side. The explanation of this fact is that a piece of soft iron, when placed in a varying magnetic field, tends to move from places of weak to others of stronger magnetic force, and other things being equal, the force so displacing the iron at any point is proportional to the product of the strength of the field, and the rate of change of the field at that point. We may show the experiment in another way. If we place a sheet of glass over the coil, and sprinkle on it some iron filings, and then pass a current through the coil, the iron filings all move outwards from the centre of the bobbin to the edge, the reasen for this being that the magnetic field of the bobbin is weaker at the centre than it is close up against the wire. This principle is employed in the construction of a large number of instruments. Some of Prof. Elihu Thomson's instruments depend on this principle.

In these instruments a small plate of soft iron is attached to an axis which passes through the centre of a bobbin in such a manner that, if the iron is displaced from the centre to the edge of the bobbin, that movement is indicated by a needle. Hence, when an alternating current is passed through the coil, forces are brought to bear on the iron, tending to displace it from the centre to the edge of the coil. A weight is so arranged as to resist this movement, and the instrument may be calibrated for different current strengths, and constitutes what is called the gravity instrument, because no springs are used in its construction.

Another very similar instrument is that devised by Von Dobrowolsky. In this instrument, which is intended for the measurement of alternating currents, there is a coil of wire (Fig. 5), and in this coil of wire is suspended a very slender fragment of iron wire. When an alternating current is passed through the coil, the iron is drawn down into the coil, owing to the tendency it has to move from weak to strong places in the field. This movement of the iron is resisted by the gravity of a small weight. A needle, attached to the axis which carries the fragment of iron wire, moves over a graduated scale, and the instrument can be calibrated as an alternating current ammeter.

Another instrument depending on the same principle is that of Nalder. In this instrument, which resembles in general construction the ammeter of Elihu Thomson, there is a fixed coil through which the current to be measured passes, and on an axis passing through this bobbin there is fixed a small plate of iron ; the field of the binder is made stronger in one part than in others by placing a fixed plate of iron in the opening of the bobbin. When a current is passed through the coil, the movable plate of iron is drawn towards the fixed plate, and in so doing turns round the axis to which it is attached. A needle fastened to the axis moves over a divided scale.

A fourth instrument depending on the electro-magnetic principle is that of Mr. Evershed. In Evershed's alternating current ammeter there is a fixed coil of wire through which an axis passes. This axis carries a small piece of soft iron like a hammer, which is fixed to the axis. Within the coil there are two soft iron cheeks, and between these is formed a strong magnetic field when a current passes through the coils. On passing the current, the movable piece of iron is drawn down between the two fixed cheeks, and this movement is resisted by a weight carried on the axis. The piece of soft iron, therefore, takes a definite position under any given current which depends on the relative forces acting upon the piece of soft iron. In these electromagnetic instruments it is important to know that in employing them for alternating currents the majority of them have to be calibrated for the particular frequency at which they are to be used. We must not take it for granted in using an instrument of this class that its readings will be identical for alternating currents of different frequencies. In the Evershed ammeter, however, a compensation is provided to meet this difficulty, and to make the instruments give identical indications, although the frequency of the alternating current may be varied. The working coil is shunted by an inductive shunt ; this shunt takes about 6 per cent. of the total current as direct currents, but only about 2 per cent. as alternate currents. The result is that the working coil takes about 2 or 3 per cent. more current with alternate currents, and eliminates any error due to eddy currents set up in the bobbin frame and case.

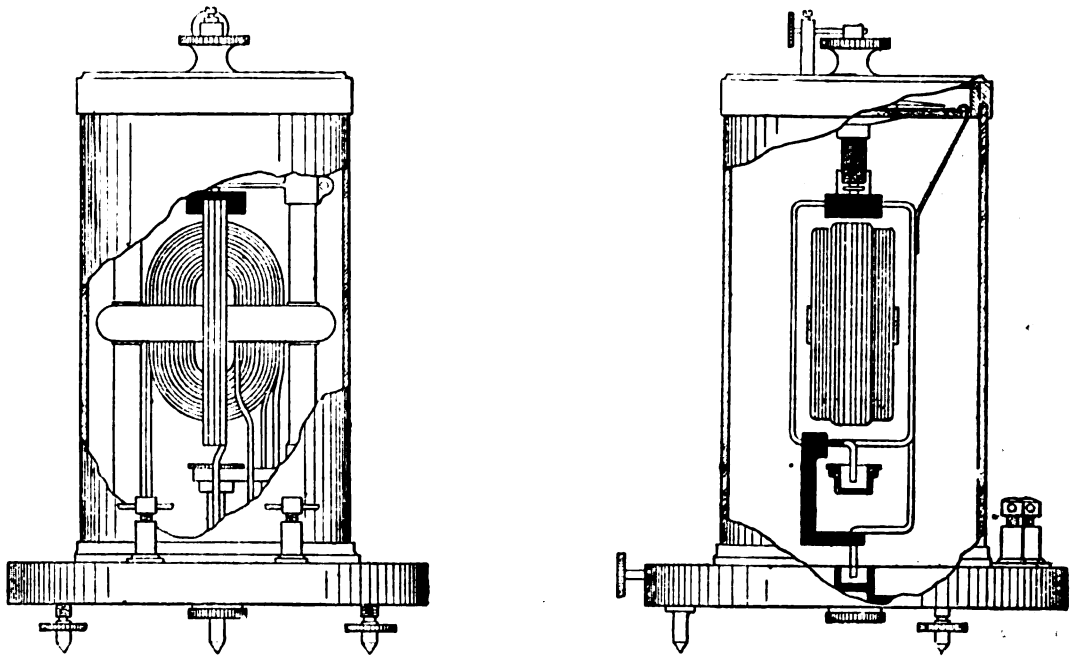

Fig. 4.

Before leaving the subject of electro-magnetic instruments for the measurement of alternating currents, I may mention one instrument which can be employed for the measurement of such small currents as those produced by a telephone. In this instrument there is a fixed coil of wire, and in the centre of this coil is suspended a very small fragment of soft iron wire, with its axis inclined at an angle of 45deg. to the plane of the coil. The wire is hung up by a cocoon fibre, and, by means of a little fragment of mirror attached to the iron, we can detect the smallest movement of the iron. On connecting a telephone to the coil and singing or speaking to it, the iron needle is deflected. The alternating current produced by the telephone passing through the coils of the instrument creates a magnetic field in the interior, and the fragment of soft iron wire tends to turn round so as to place its greatest lengths in the direction of the field of the corner. Hence the presence of a small alternating current can be detected. By making suitable arrangements and suspending the fragment of wire by a quartz fibre, it is possible to make an instrument sufficiently sensitive to measure the millionth part of an ampere.

I now pass on to consider those instruments for the measurement of alternating currents of strength which depend upon the thermal principle, that is to say, depend for their action upon the heating of a conductor through which the current passes. The first of these, which I will describe, is the one which is called the twisted strip ammeter of Prois. Ayrton and Perry. In this instrument a strip of platinoid is stretched between two supports and twisted round in the middle, so that the two halves of the strip form right and left-handed spirals. When this is

Digitized by Google

done, and the strip fixed at its two extremities, if an electric current is passed through it, and heats it, the strip tends to twist up more. If an index needle is attached to the centre of the strip, then the passage of a current through the strip may be made to cause this needle to move over a scale, and the position of the needle at any extent to indicate the current going through the strip. If the strip is enclosed in a tube made one-third of iron and two-thirds of brass, the ends of the strip being

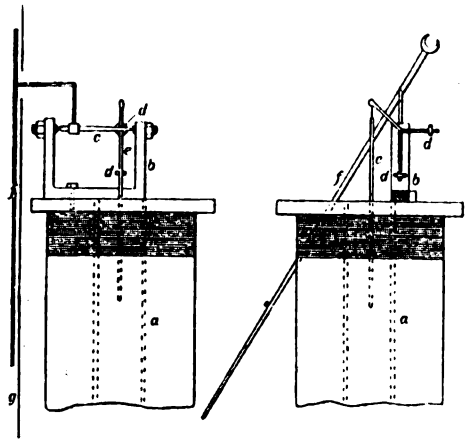

Fig. 5.

attached to the ends of the tube by an insulating support, then no raising or lowering of the temperature of the strip and tube, as a whole, will affect the length of the strip, and hence such an arrangement will constitute a compensation for external temperature. If, however, the strip be supposed to be cooled or heated apart from the tube, it will untwist or twist up more. In order to be able to observe the movements of the strip relatively to the tube, a slit is to be cut in the side of the tube through which the needle attached to the strip can project. In

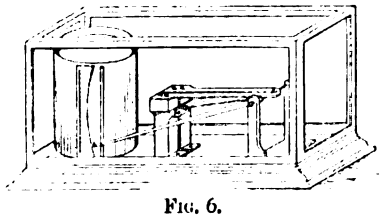

Fig. 6.

the real instrument the tube containing the strip is fixed on to a stout bracket which divides it into two parts, the compound tube having the same coefficient of expansion as platinoid. A needle attached to the centre of the strip projects through a cut in the tube, and moves over a divided scale. If a current is passed through the strip it heats it, and after a short time the strip assumes a certain definite temperature which is attained when there is a balance between the rate at which the heat is generated in the strip, and the rate at which it is radiated to the walls of the enclosing tube. Accordingly, there is a definite position of the needle corresponding to any particular mean

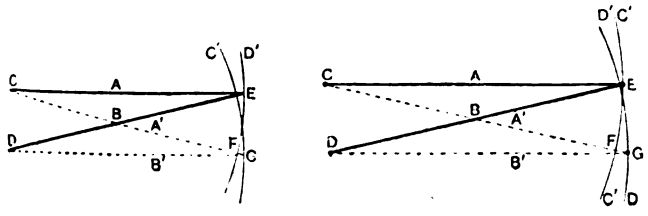

Fig. 7.

square value of the strength of the current, and by passing steady currents through the instrument it can be calibrated for use with alternating currents. Such an ampere meter can be made to read from about 0·2 to 5 amperes, reading by hundredths of an ampere. For the ready measurement of small currents the instrument is convenient, but there are certain difficulties connected with its use which are common to all such thermal instruments.

We may next take note of a very ingenious hot strip ammeter, invented by Major Holden. In this instrument there are two metal strips, and (*see* Fig. 6) of the same length, section, and material. These strips are fastened together by rivets, or otherwise secured at the point, E (*see* Fig. 7), and they are also fastened at the other ends to the framework of the instrument. These strips of metal are each of them of a horse-shoe shape, and, from proper terminals, a current can be passed through one of these strips. If this is the case, the strip becomes heated, and, if one strip is heated, say the top one, whilst the other one remains practically of the same length, the compound strip will be obliged to assume a new position, as indicated by the dotted lines in Fig. 7. This distortion of the compound strip is made to affect a system of levers which multiplies the motion, and an index arm may thereby be caused to move over a scale, or to move a writing pen over a revolving cylinder. It will be seen that a general rise of temperature of both strips simultaneously, such as would be produced by taking the instrument into a warm place, will not affect the form of the compound strip, since each strip lengthens equally, and therefore there will be no turning movement.

In Fig. 8 we have a plan showing the horse-shoe shaped strip, the ends of which are attached to insulated blocks of metal, which form the terminals of the instrument. The controlling strip, which is fastened underneath, and is indicated by the letter B, is a plain strip, riveted at one end to A and the other end to an insulated piece carried on the terminal blocks. Such an arrangement of com-

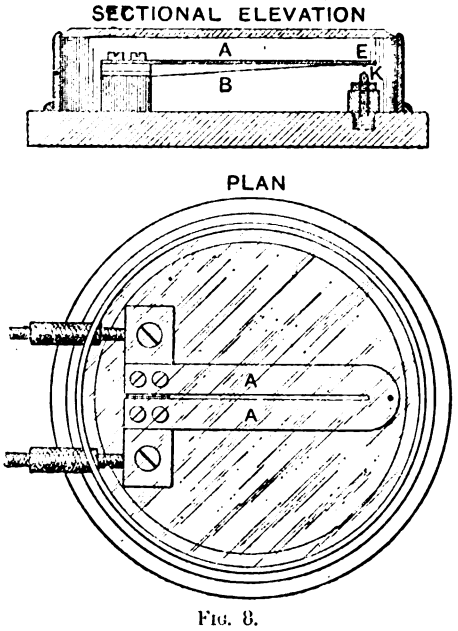

Fig. 8.

pound strips may be employed, not only as an alternating current ammeter, but as a means for closing the circuit when a current is increased above a certain amount. A recording ammeter, made on this principle, which is an exceedingly simple and effective instrument for recording the strength of large alternating currents, and the rigidity of the strip causes the ammeter to be remarkably dead-beat. In the next lecture I shall proceed to describe how these principles are employed in the construction of instruments for the measurement of alternating-current pressure.

(To be continued.)

LEGAL INTELLIGENCE.

Cheslea Electricity Supply Company (Limited) v. London Electric Supply Corporation (Limited).

This was a motion before Mr. Justice Wright on Wednesday last on behalf of the plaintiffs for an injunction to restrain the defendants, their workmen, servants, and agents from laying any distributing main or mains for the supply of electric light within the area described in Schedule A of the Chelsea Electric Lighting Order, 1886, except as provided by an agreement between the plaintiffs and the defendants, dated July 9, 1889, until the trial of the action. In 1889 certain litigation was pending between the plaintiffs and the defendants, and for the settlement of these disputes an agreement, dated July 9, 1889, was entered into between the two companies. By Clause 2 of the agreement (*inter alia*) the London Company undertook that they would not, without the consent of the Chelsea Company, for a period of seven years from the date of the confirmation of a Provisional Order, which was then being applied for by the London Company, voluntarily supply electricity within the area described in Schedule A of the Chelsea Company's Act, and that they would not take any direct action to cause themselves to be required to supply electricity within such area, or to hinder the Chelsea Company

Digitized by Google

from supplying within such area, or to compete voluntarily with the Chelsea Company within such area. On the 7th inst. the defendants opened ground southwards in Sloane-square, nearly at right angles to the pipe or pipes in their trunk main near Upper George-street, and they have since carried on the work of opening the ground as far south as the Court Theatre. The plaintiffs' secretary made an affidavit, saying that he believed that, unless restrained by injunction, the defendants would insert distributing mains in pipes or a pipe along the ground they had so opened up and elsewhere in the plaintiffs' area of supply. This, the plaintiffs submitted, would be in breach of the agreement of July 9, 1889. On behalf of the defendants it was contended that the agreement was void as being contrary to the provisions of the Electric Lighting Act, 1882 (45 and 46 Vict., c. 56), Section 11, which provides that "no local authority, company, or person shall by any contract or assignment transfer to any other company or person, or divest themselves of any legal powers given to them, or any legal liabilities imposed on them by this Act, or by any licence, order, or special Act, without the consent of the Board of Trade."

Mr. Justice WRIGHT said that both Companies were bound by Section 11 of the Act of 1882. The defendant Company had agreed that it would not voluntarily supply electricity within a certain area, and it now said that was a void agreement. He thought not. If that was so, the London Company had not overridden the Act by this agreement. The contract was that they would not, until required, supply the electricity. He could not hold this agreement bad. There must be an injunction, in terms of the motion, until the trial.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. *Comparison with any similar electrical publication is specially invited.*

TENDERS INVITED.—The Public Works Department of the Egyptian Government invite offers for the establishment and working of tramway lines in Cairo. The Act of Concession may be had on application from the Minister of Public Works, to whom offers must be sent by February 1st next.

——— The Council of the Borough of Brighton invite tenders for the supply and erection of fittings for lighting the Municipal School of Science and Art on the Grand Parade, Brighton, by electricity. Some further particulars will be found in our advertising columns, and all information can be had on application at the office of Mr. F. J. Tillstone, town clerk, Town Hall, Brighton, to whom tenders must be sent in by 4 o'clock on Thursday, the 31st inst.

TENDERS ACCEPTED.—The Southampton Harbour Board have accepted the tender of Messrs. Donnison, Parmiter and Barber, of Southampton, for the erection of a private telephone between the Board offices and the pier and quay for £30. 15s., including two years' maintenance.

SALES BY AUCTION.—Tuesday, Wednesday and Thursday, September 12th, 13th, and 14th, have been fixed for the sale by auction by Messrs. Wheatley Kirk, Price and Goulty, on the Works premises, Square-road, Halifax, Yorkshire, of the entire contents of the Northern Telegraph Works, including valuable and modern engineering and electrical fixed and loose plant, machinery, dynamos, motors, electrical fittings, stores, batteries, and drawings, patent rights, and other effects, in the matter of Blakey, Emmott and Co. (in liquidation). Catalogues can now be obtained from the auctioneers, 49, Queen Victoria-street, London, E.C., and Albert-square, Manchester; and further particulars can also be had from Messrs. Lakeman and Olliver, 44, Prudential-buildings, Park-row, Leeds.

——— Messrs. Wheatley Kirk, Price and Goulty will sell by auction at an early date on the premises, 11 and 12, New Bridge-street, Ludgate-circus, London, E.C., the modern engineering and electrical plant, loose tools, dynamos, gas engines, &c., to be disposed of under the liquidation of Fawkner, Rogers and Co. Further particulars can be obtained of the auctioneers, 49, Queen Victoria-street, E.C., or of Messrs. Gane, Jackson and Jefferys, 53, Coleman-street, E.C.

LIQUIDATIONS.—The creditors of the London Battery Company (Limited) are requested to send their names and addresses and particulars of their debts, not later than October 17th next, to Mr. H. G. Ellis, of 1 and 2, Marlborough-street, Blackfriars, S.E., the liquidator.

——— The Windsor and Eton Electric Lighting Company (Limited) has suspended operations, and is now in liquidation. Current was supplied for the last time on Saturday.

LIQUIDATIONS.—Amongst the trade creditors in the failure of the London Metallurgical Company (Limited), are the following:—

	£	s.	d.
Arcas Plating Company (Limited)	1,188	0	0
Messrs. Ernest Scott and Mountain (Limited)	92	11	0
Messrs. Pfeil and Co.	79	12	10
Messrs. Woodhouse and Rawson United (Limited)	41	18	4
Electrical Power Storage Company (Limited)	38	16	0
National Telephone Company (Limited)	30	15	0
Messrs. Cathcart, Peto and Radford	23	8	7
Messrs. Vaughan and Brown	14	3	5
Messrs. Johnson, Matthey and Co. (Limited)	12	4	2

——— Under the liquidation of the Art Workshops (Limited) accounts have been issued, showing total liabilities £8,772. 3s. 2d., and assets £3,880. 18s. 1d., the latter being absorbed by the claims of the debenture-holders. The total deficiency is £24,938. The failure is ascribed to the action of the debenture-holders in taking possession of the assets at a moment's notice, to insufficiency of capital, and to want of careful management.

TELEPHONE COMPANY OF IRELAND (LIMITED).—The resolution passed on July 20th for the winding up of this Company was confirmed on August 5th. Messrs V. B. Dillon, Arthur Dudgeon, and Gilbert Cockburn were appointed liquidators.

COMPOSITION.—A meeting will be held at Messrs. Nairn and Bowes' offices, 140, Hope-street, Glasgow, on the 26th inst., at 12 o'clock, to consider an offer of composition by Mr. W. McWhirter, electrical engineer, Campbell-street, Govan.

APPOINTMENTS.—Mr. A. E. Pullen has been appointed by the City Council assistant electrical engineer for Huddersfield, at a salary of £130 per annum. Forty-six applications were received, which were ultimately reduced to four, out of which number Mr. Pullen was selected.

——— Mr. Dalton has been appointed tester in the Bradford Corporation Electrical Works, at a salary of £150 per annum; the appointment to be for three months.

APPOINTMENTS VACANT.—The Toxteth Local Board require an electrical inspector in connection with the Toxteth Park Electric Lighting Provisional Order. Applications must reach Messrs. North, Kirk and Cornett, clerks to the Board, 15, Lord-street, Liverpool, not later than noon on Wednesday, the 30th inst. Further particulars are given in our advertisement columns.

——— A science master is required for the borough of Brighton Municipal School of Science and Art, salary £200 per annum; also a science master for evening classes in mathematics, magnetism and electricity, &c., salary £120 per annum. Further particulars can be obtained of Mr. F. J. Tillstone, town clerk, Town Hall, Brighton, to whom applications must be sent in not later than 10 o'clock a.m. on the 28th inst.

MESSRS. G. E. BELLISS AND CO.—Notice is given that the partnership hitherto subsisting between Mr. George Edward Belliss and Mr. Alfred Morcom, trading as G. E. Belliss and Company, Ledsam-street Works, Birmingham, has been dissolved by mutual consent, and all debts due to and owing by the late firm will be received and paid by Messrs. G. E. Belliss and Co. (Limited), which has acquired and will continue the business as from June 30th last. Particulars of the reconstructed firm will be found in our issue of the 18th inst., page 431.

MESSRS. CLARKE, CHAPMAN AND CO. (LIMITED).—This firm report that their electrical department is well employed, and that, judging by the number of ship installations they are carrying out on the Tyne and elsewhere, their latest type of slow-speed combined engines and dynamos seems to be giving general satisfaction. Sixteen steamers of various classes are at the present time being fitted up with the electric light, including the Japanese cruiser the "Yoshino," building at Sir W. G. Armstrong, Mitchell and Co.'s Elswick Yard (for which Messrs. Clarke, Chapman and Co. are supplying the search-light projectors), and three large passenger steamers building to the order of the Norddeutscher Lloyd Company. Amongst recent contracts obtained is the lighting of Messrs. Ferguson Bros.' large dye works at Carlisle. The firm are issuing a small book containing instructions for the management and control of generating plant and installations in general, and of their own make in particular, besides other electrical memoranda. It is a handy pocket size.

MESSRS. DRAKE AND GORHAM.—This firm have secured the lighting contract for Balliol College, Oxford, and fittings are to be made to suit the special character of the building.——Branch offices have been opened at 100, King-street, Manchester.

LOST.—Messrs. Drake and Gorham, of 66, Victoria-street, Westminster, S.W., have lost a book containing some original testimonials, and anyone returning the same to them, or giving such information as will lead to its recovery are offered £5 as a reward.

A. P. LUNDBERG'S CATALOGUE.—We have received an illustrated price list of Mr. Lundberg's well-known switches, sockets, and

Digitized by Google

other fittings. The "Unique" switch, his principal speciality, is, as far as we know, the only practical switch that cannot possibly be held in such a position than an arc can be wilfully produced, having a sudden snap on and off. The catalogue shows one or two of the modifications of this switch for special purposes, such as a "two-way." Several wall sockets are made by Mr. Lundberg, the one with a "Unique" switch would be an admirable one were it not that the cord is continually twisted in one direction. The "centric" wall socket presents several good points, but, as in some other of these manufactures, vulcanised fibre is employed. If slate or some reliable insulator could be employed, this would be seen to be a very useful appliance, being more simple than most wall-socket switches. Lengthening plugs and twin socket plugs are among the other useful fittings offered in this catalogue.

AYR.—The Town Council have received a notification from the Board of Trade that they are prepared to grant further time for the carrying out of the provisions of Section 17 of the Ayr Electric Lighting Order, and have extended the time for one year from August 4th last.

BRECHIN.—At the last meeting of the Public Commission Mr. Jamieson gave notice that he intended moving that an electric light installation, sufficient both for the new police offices and library, be erected, and that the Lighting Committee be empowered to obtain specifications to be drawn up by an electrical engineer.

COOKING BY ELECTRICITY.—The *Pall Mall Gazette* of the 17th inst. contains an article earnestly advocating the extension of electric cooking, and calling upon those supplying the necessary apparatus to bestir themselves and "take the tide at the flood." The article is based upon the recent five-course dinner cooked by electricity in Manchester. "It is by such displays that electric cooking must stand or fall, and there are many reasons for hoping that it will stand."

COVENTRY.—The Electric Lighting Committee of the City Council have presented a detailed report on their investigations into the lighting of the city by electricity. The Provisional Order expired on June 11th last; but the Committee think it unlikely that the Board of Trade will revoke the Order if the Corporation now proceed to exercise their powers with due expedition. The Committee are of opinion that the time devoted to inquiries has been profitably spent, and that the time has now come when operations for the lighting of the city by electricity should be commenced. Schemes had been received from the Brush Company, Messrs. S. Z. de Ferranti, and Messrs. Hammond and Co., recommending a high-tension alternating-transformer system, with a station near the cotton mill; and one from the Electrical Power Storage Company, recommending a high-tension direct-current system, with sub-stations and storage batteries, the generating station to be at Pool Meadow; whilst the Electric Construction Company and Messrs. J. H. Holmes and Co. recommended a low-tension direct-current system, with or without storage batteries, the generating station to be at Pool Meadow. In comparing the estimates which accompanied these schemes the Committee considered the high-tension alternating transformer system involved the smallest capital outlay, and was the best adapted to the needs of the city. Alternative schemes have also been submitted by Messrs. Siemens Bros. and Co., one on the high-tension alternating transformer system, the other on a system combining high-tension alternating generation with low-tension continuous-current distribution, and the estimates forwarded with the schemes confirm the Committee in their views as to the greater cheapness of the high-tension alternating transformer system. In the selection of the type of boilers and engines to be adopted the Committee show a preference for engines of the horizonal slow-speed type, with Lancashire boilers. It is recommended that operations begin with a small generating station, with a view to adding to the plant from time to time as required, so as to reduce the initial outlay as much as possible. Having proceeded so far the Committee invited those firms who had recommended a high-tension alternating current system to submit amended estimates and specifications for a station capable of supplying current to about 4,300 8-c.p. lamps with a distributing system adapted for 12,000 similar lamps, and in the end selected those of the Brush Company and Messrs. Hammond and Co. (the latter coupled with Messrs. John Fowler and Co., of Leeds). A site for a central station in Sandy-lane, which is near both railway and canal, is being negotiated for. The estimates submitted by the various firms do not include buildings, or builders' work. The Committee accordingly recommended that the above arrangement be adopted, and that they be empowered to employ a consulting engineer to advise them upon the selected plans and specifications, and an architect to prepare plans and specifications for the necessary buildings. The Committee believe that the amount required will not exceed £15,000, including buildings, &c. A discussion ensued, in which support was almost unanimously given to the recommendations of the Committee, and the report was ultimately adopted without dissent.

DERBY.—In connection with the electric lighting of this town the work is so well in hand that operations have already commenced for the erection of the large lamp pillars (of which 160 will be erected) to carry the Brockie-Pell lamps, which are being used for the street lighting.

DERRY.—Satisfactory progress is being made with the electric lighting works, generating plant, electric lighting machinery and apparatus, &c., and it is anticipated that the light will be supplied about October. Many of the owners of the large mills and factories in the district have either decided to adopt the light or have the matter under consideration.

DUBLIN.—The Public Libraries Committee of the Corporation recommend that Capel-street Library be lighted electrically. The discussion on the report, which was informal, was adjourned.

EASTLEIGH.—The Local Board last week discussed the question of the indifferent lighting of the principal thoroughfares of the district. Mr. Hazel was strongly in favour of the electric light, which he stated would cost rather less than the present cost of gas. A proposal that the electric light be substituted for gas, and that the Local Board borrow £4,000 for electric lighting purposes, was, however, defeated.

EDMONTON.—At the last meeting of the Board of Guardians, the subject of the advisability of electrically lighting the Edmonton House was discussed, and the Clerk was instructed to obtain estimates for two installations. The subject of introducing the electric light is discussed in the local Press, with special reference to the lighting of the new library and town hall about to be built.
